JANUARY, 1923, to JUNE, 1923

"To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

London
MACMILLAN AND CO., LIMITED
NEW YORK: MACMILLAN COMPANY

Nature,
August 11, 1923

INDEX.

NAME INDEX.

Abbot (Prof. C. G.) and others, Investigations on Solar Radiation, 414
Abbot (W. N.), Announcement of a New Comet, 857
Åberg (Dr. N.), Die Franken und Westgoten in der Völkerwanderungszeit, 454; La Civilisation énéolithique dans la Péninsule Ibérique, 563
Abraham (Prof. M.), [obituary article], 506
Ackermann (A. S. E.), Experiments on Hardness and Penetration, 17; Physical Properties of Clay and Clay-Mud, 202; Pressure of Fluidity of Metals, 534
Acton (Dr. Elizabeth), [obituary], 781
Adair (G. S.), elected a Fellow of King's College, Cambridge, 449
Adam (N. K.), Adsorption and Hæmoglobin, 844; The Combination between Oxygen and Hæmoglobin, and the Criteria of Adsorption, 496; The Structure of Thin Films. Pts. IV. and V., 793
Adams (J.), The Age and Area Hypothesis, 114
Adams (W. S.) and A. H. Joy, Spectroscopic Parallaxes of A-type Stars, 128; The Radial Velocities of 1013 Stars, 892
Adamson (R. S.), resignation of lectureship in botany in Manchester University, 418
Addey (F.), Measurement of Vertical Dimensions with Microscope, 236
Addison (M.), Human Heads carved in Steatite from Sierra Leone, 170
Adrian (Dr.), re-appointed University lecturer in physiology in Cambridge University, 864
Ainsley (F. J.), Mast and Aerial Construction for Amateurs: together with the Method of Erection and other Useful Information, 628
Aldous (Rev. J. C. P.), [death], 298
Aleksejevski (E. V.), Destructive Distillation of Bones, 684
Alexander (C. P.), New or Little-known Species of Australian Tipulidæ (Diptera). Pt. I., 136
Alexander (J. W.), A Lemma on Systems of Knotted Curves, 764
Alexander (P. J.), The Dates of Appearance and Habitats of the Mycetozoa of Surrey, 553
Algué (Rev. J.), Weather in the Philippines, 129
Allan (G. G.), appointed assistant bacteriologist in Sheffield University, 380
Allbutt (Sir T. Clifford), Notes on the Composition of Scientific Papers. Third edition, 490
Allen (Dr. E. J.), awarded the Hansen prize, 509
Allen (Dr. F. J.), Longevity in a Fern, 742
Allen (Prof. H. S.), A Static Model of the Hydrogen Molecule, 830; The Development of the Quantum Theory, 279
Allen (W. H.), gift to the Institution of Mechanical Engineers, 449
Aloy (M.) and M. Valdiguié, The Oxidations and Reductions produced by Uranium Salts under the Influence of Light, 727
Amar (J.), The Law of Vivireaction in Biology and Pathology, 554
Ames (A.), C. A. Proctor, and Miss Blanche Ames, The Laws of Vision and the Technique of Art, 581
Ames (Prof. J. S.), Recent Aeronautic Investigations and the Aeroplane Industry, 363
Ames (W. M.), Applications of the Microscope in the Manufacture of Rubber, 794
Amundsen (Capt. R.), arrival of, at Nome, 370; projected flight across the North Pole, 784; abandonment of the, 890
Andant (A.), The Application of Photography to the Study of Critical Opalescence, 347
Anderson (E. M.), The Geology of the Schists of the Schichallion District of Perthshire, 485
Anderson (Dr. J. S.), appointed professor of medicine at Hong-Kong University, 552
Andersson (J. G.) and others, Palæontological Research in China, 160
André (E.), Separation of Methyl Oleate and Methyl Linoleate by Fractional Distillation, 452
Andrée (Prof. K.), Geologie in Tabellen für Studierende der Geologie, Mineralogie, und des Bergfachs, der Geographie und der Landwirtschaft. Erster, Zweiter, und Dritter Teil, 630
Andrews (Dr. C. W.), Guide to the Elephants (Recent and Fossil) in the British Museum (Natural History). Second edition, 26
Andrews (E. A.), Factors affecting the Control of the Tea Mosquito Bug (Helopeltis theivora, *Waterh.*), 875
Annandale (Dr. N.), Bivalve Molluscs injuring Brickwork in the Calcutta Docks, 555; elected president of the Asiatic Society of Bengal, 408; Introduction to the Study of the Fauna of an Island in the Chilka Lake, 378; Land Molluscs, 656; Plant and Animal Designs in the Mural Decorations of an Uriya Village, 832; The Marine Element in the Fauna of the Ganges, 893
Anrep (G. V.), The Irradiation of Conditioned Reflexes, 274
Anthony (Prof. R.), Le Déterminisme et l'adaptation morphologiques en biologie animale. Première partie, 664
Appleton (Dr. A. B.), D. G. Reid, A. Hopkinson, and V. C. Pennell, re-appointed demonstrators in anatomy in Cambridge University, 900
Argand (Prof. E.), elected a foreign correspondent of the Geological Society, 716
Armstrong (Dr. E. F.), The Structural Units of the Body, 768; and Dr. T. P. Hilditch, Catalytic Actions at Solid Surfaces. X., 168; XI., 793
Armstrong (Prof. H. E.), Electrolytic Conduction: Sequel to an Attempt (1886) to apply a Theory of Residual Affinity, 689; The Origin of Osmotic Effects. IV., 689
Asahina (Y.) and others, Chemistry of some Japanese Plant Products, 823
Ashby (Dr. H. T.), Infant Mortality. Second edition, 530
Ashby (S. F.), Oospore Formation in Phytophthora, 61
Ashcroft (E. V.), appointed a demonstrator in anatomy in Manchester University, 901
Ashley (Sir William), Psychology in Engineering, 302
Ashton and Parsons, Ltd., gift to Guy's Hospital for research, 25
Ashworth (Prof. J. H.), A Causal Organism of Nasal Polypus, 719
Ashworth (Dr. J. R.), The Relation of the Critical Constants and the True Specific Heat of Ferromagnetic Substances, 773
Aston (Dr. F. W.), A Critical Search for a Heavier Constituent of the Atmosphere by Means of the Mass-Spectrograph, 689; Mass Spectra, 684; presented with the John Scott medal, 680; The Isotopes of Germanium, 771; The Light Elements and the Whole Number Rule, 739

Athanasiu (G.), The Sensibility of Photographic Plates containing Mercury Salts, 795
Atkins (Dr. W. R. G.), The Hydrogen-ion Concentration of Sea Water, 132; The Hydrogen-ion Concentration of the Soil in Relation to the Flower Colour of *Hydrangea hortensis* W., and the Availability of Iron, 487; Time Relations in a Dream, 117; and M. V. Lebour, Soil Reaction, Water Snails, and Liver Flukes, 83
Atkinson (R. d'E.), Selective Interruption of Molecular Oscillation, 326
Aubert (M.) and G. Dixmier, The Stability of Alcohol-Petrol Mixtures in the Presence of Water, 762
Auchinleck (G. G.), The Oil Palm under Cultivation, 893
Audubert (R.), The Action of Gelatin upon Concentration Cells, 520
Aufschlaeger (Dr. G.), the seventieth birthday of, 232
Automatic and Electric Furnaces, Ltd., Hardening Stainless Steel, 824
Aversenq (J. P.), L. Jaloustre, and E. Maurin, Some Effects of Thorium-X on Diastases and Micro-organisms, 207
d'Azambuja (L.), New Measurements of the Velocity of Rotation of the Filaments, 588

B. (F. A.), The Name of the Pond Snail, 150
Babington (C. C.), Manual of British Botany: containing the Flowering Plants and Ferns arranged according to the Natural Orders. Tenth edition, edited by A. J. Wilmott, 251
Bacon (Dr. R. F.) and W. A. Hamor, American Fuels. 2 vols., 835
Bacot (the late A. W.), proposed memorial to, 749
Baillaud (B.), presented with the gold medal of the Astronomical Society of the Pacific, 337
Baird (H. S.), The Occipital Bones of the Dipnoi, 311
Baird and Tatlock's Standard Catalogue of Scientific Apparatus, 26
Bairstow (Prof. L.), appointed Zaharoff professor of aviation at the Imperial College of Science and Technology, 723; The Low-power Aeroplane or Aviette, 672; The Third Air Conference, 238; Miss B. M. Cave, and Miss E. D. Lang, The Resistance of a Cylinder moving in a Viscous Fluid, 241
Baker (Dr. E. A.), The Highlands with Rope and Rucksack, 800
Baker (E. G.), The Flora of Gough Island, 206
Baker (Dr. H. A.), Continental Flotation and Drift, 80
Baker (H. W.), appointed lecturer in engineering in Manchester University, 240
Baker (Dr. T. J.), A Permanent Image on Clear Glass, 743
Baker (T. Y.), Prismatic Astrolabe designed and made at the Admiralty Research Laboratory, Teddington, 346
Baker (W. C.), "Artificial" Vertical Beam, 185
Baldet (F.), The Study of Atmospherics, 554
Balfour (Dr. A.), Cure of Sleeping Sickness, 339
Balfour (Earl of), degree conferred upon, by Cracow University, 688; science and practical life, 439
Balfour (H.), Civilisation and Primitive Peoples, 753
Ballard (E.), appointed adviser in plant pathology at the Agricultural and Horticultural Station, Long Ashton, 273
Balls (Dr. W. L.), The Determiners of Cellulose Structure as seen in the Cell Walls of Cotton Hairs, 653
Bancroft (Prof.), Contact Catalysis, 236; and F. Warren, The Dissipation of Clouds, 265
Bandulska (Miss Helena), The Cuticular Structure of certain Dicotyledonous and Coniferous Leaves from the Middle Eocene Flora of Bournemouth, 206
Banerji (Dr. S. K.), The Origin of Cyclones, 413; Vertical Change of Wind and Tropical Cyclones, 668
Bannerman (D. A.), The Canary Islands: their History, Natural History, and Scenery: an Account of an Ornithologist's Camping Trip in the Archipelago, 77
Bannerman (Surg.-Gen.), The Story of Bubonic Plague, 197
Banting (Dr.), establishment for, of a research chair at Toronto, 751
Barbot (G.), a return journey by monoplane across the English Channel, 645
Barcroft (J.), Adsorption and Hæmoglobin, 844; Effect of High Altitude on the Physiological Processes of the Human Body, 134; re-appointed reader in physiology in Cambridge University, 864
Barker (A. H.), Tests on Ranges and Cooking Appliances, 415
Barker (T. V.), Molecular and Crystal Symmetry, 632
Barley (A. H.), The Drayson Problem, 94, 291
Barnard (Prof. E. E.), [death], 298; [obituary article], 367
Barnard (J. E.), Sub-bacteria, 103
Barnard (K. H.) and others, The Distribution of Life in the Southern Hemisphere, and its Bearing on Wegener's Hypothesis, 131
Barnes (Canon E. W.), Religion and Evolution, 526
Barr (Prof. A.), elected president of the Optical Society, 337
Barrett (Sir James W.), The Resonance Theory of Hearing, 396
Barrett (W. H.), Elementary Organic Chemistry, 321
Bartsch (Dr. P.), Digestion of Wood by the Shipworm, 28
Barus (Prof. C.), A Comparison of the Relative Sensitiveness of Telephones, 36; Gaseous Viscosity measured by the Interferometer U-tube, 763; The Equilibrium Positions of the Vacuum Gravitation Needle in 1921 and 1922, 36
Baschin (O.), The Crumpling and Rifting of Earth-Blocks, 548
Bateman (H.), The Nature of Light-Quanta, 567
Bates (D. C.), Weather Research on the Kermadec Islands, 648
Bateson (Dr. W.), Area of Distribution as a Measure of Evolutionary Age, 39; Dr. Kammerer's Alytes, 738, 878
Bather (Dr. F. A.), Echinoderm Larvæ and their Bearing on Classification, 397; The Rule of Priority in Nomenclature, 182
Batten (H. M.), The Badger: Afield and Underground, 800
Batten (Lily), The Genus Polysiphonia, 67
Baudouin (C.), translated by E. and C. Paul, Studies in Psychoanalysis: an Account of Twenty-seven Concrete Cases preceded by a Theoretical Exposition, 316
Baudouin (M.), Radiography applied to the Study of the Lesions of Prehistoric Human Bones, 488
Baxandall (D.), Telescopes before the Early Part of the 19th Century, 784
Baxandall (F. E.), Lines of Unknown Origin in various Celestial Spectra, 717
Baxendell (J.), Report of Meteorology at Southport, 1921, 341
Bayliss (Sir W. M.), Adsorption and Hæmoglobin, 666; Colloids and Staining, 382; Insulin, Diabetes, and Rewards for Discoveries, 188
Beadnell (Surg. Rear-Admiral C. M.), Physics and Psychics, 139
Beauverie (J.), Influence of the Rainfall during the "Critical Period" of Wheat on the Yield, 452; The Relations existing between the Development of Wheat Rust and Climate, 383
Beck, Ltd. (R. and J.), A New Microscope, 62
Becker (H. G.) and E. F. Pearson, Irregularities in the Rate of Solution of Oxygen by Water, 487
Becquerel (P.), Observations on the Necrobiosis of Plant Protoplasm with the Aid of a New Reagent, 451
Bedel (C.), A Polymer of Hydrocyanic Acid, 207
Beilby (Sir George), resignation of the directorship of Fuel Research and chairmanship of the Fuel Research Board, 855: The Structure of Coke, its Origin and Development, 133
Belaiew (Col. N. T.), Crystallisation of Metals: being a Course of Advanced Lectures in Metallurgy delivered at the Royal School of Mines, Imperial College, under the auspices of the University of London, in Feb. and March 1922, 876
Bell (Dr. Julia), Anomalies and Diseases of the Eye. Nettleship Memorial Volume. Part I.: With a Memoir of Edward Nettleship by Dr. J. B. Lawford, 492

Belling (J.) and A. F. Blakeslee, The Reduction Division in Haploid, Diploid, Triploid, and Tetraploid Daturas, 867
Bellingham (L.), Use of the Triode Valve in Spectrometry, 534
Bemmelen (Dr. W. van), retirement from the directorship of the Royal Magnetical and Meteorological Observatory, Batavia, 29
Bender (Prof. H. H.), The Home of the Indo-Europeans, 111
Benedict (F. G.) and E. G. Ritzman, Under-nutrition and its Influence on the Metabolic Plane of Steers, 554
Benest (E. E.), The "Sumatras" of the Malacca Straits, 727
Bennet-Clark (T. A.), A. D. Hobson, and L. H. Matthews awarded Frank Smart prizes in Cambridge University, 900
Bennett (Dr. G. T.), Paradromic Rings, 882
Benson (Dr. W. N.), The Devonian Formation in Australia, 719
Berland (L.), The Origin of the Spiders of New Caledonia, 904
Berry (A.) and Lorna M. Swain, The Steady Motion of a Cylinder through Infinite Viscous Fluid, 205
Bert (L.), A New Synthesis of Cumene and *p*-Cymene, 520
Bertrand (G.) and Mlle. S. Benoist, A New Sugar, Procellose, 903
Besson (L.), The Loss of Light in Paris and its Neighbourhood, 207
Best (E.), Dominion Museum Monographs 1 to 4, 790
Betts (Annie D.), A Puzzle Paper Band, 882
Beveridge (Sir William), The Universities and Training for Administrative and Municipal Life, 722
Bhatia (Prof. B. L.), A New Gregarine Parasite of Leptoplana, 116
Bidder (Dr. G. P.), The Wegener Hypothesis and the Great Pyramid, 428
Biggs (H. F.), Time Relations in a Dream, 290
Bigot (A.), Action of Heat on Kaolins, Clays, etc., 171, 383, 831
Bigourdan (G.), The "Cabinet du Roi" and the Forgotten Discoveries of Rochon, 310; The Propagation of Hertzian Waves over Great Distances, 691
Bingham (Prof. H.), Inca Land: Explorations in the Highlands of Peru, 665
Bird (H. F.), proposal to confer an honorary degree upon, by Cambridge University, 760
Birge (R. T.), The Value of e/m, 287; The Value of the Planck Constant h, 811
Bishop (H. E.), The Present Situation in the Radium Industry, 614
Bjerknes (Prof. V.), Meteorological Physics, 871
Black (Lt.-Col. J. A.), Crime and Poisoning, 268
Blackett (P. M. S.), elected a fellow of King's College, Cambridge, 449; The Natural Curvature of α-ray Tracks, 519; The Study of Forked Alpha-ray Tracks, 381
Blackman (Dr. A. M.), The Plundering of the Royal Tombs at Thebes, 234; The Sun-Cult in Ancient Egypt, 499, 536
Blackmore (H. S.), Violet Dimbleby, and Prof. W. E. S. Turner, A Rapid Method of Testing the Durability of Glassware, 519
Blake (Major W. F.), The Attempted World Flight, 25
Bland-Sutton (Sir John), Spolia Nemoralia: Shrunk Heads, Ear-plugs, and Labrets, 95
Bledisloe (Lord) and others, The Rothamsted Experimental Station, 863
Bloch (L. and E.), Spark Spectra of Higher Order, 520
Blomefield (L.), A Naturalist's Calendar, kept at Swaffham Bulbeck, Cambridgeshire. Second edition, edited by Sir Francis Darwin, 112
Blondel (A.), The Electro-phonographic Method and its Use for the Registration of Sounds, 103
Blum (Mlle. Lucienne), Modification of Plants submitted to Culture under Glass, 655
Blyth (C. E.), Dr. G. Martin, and H. Tongue, Law governing the Connexion between the Number of Particles and their Diameters in Grinding Crushed Sand, 842
Böeseken (Prof. J.), Valency of Boron, 894
Bogitch (B.), The Removal of Sulphur from Metals by Lime, 171
Bogue (Dr. R. H.), The Chemistry and Technology of Gelatin and Glue, 456
Bohr (Prof. N.), an honorary degree to be conferred upon, by Manchester University, 418; The Theory of Spectra and Atomic Constitution: Three Essays, 523; proposed as an honorary member of the Cambridge Philosophical Society, 828; Latin oration on the conferment of an honorary degree on, in Cambridge University, 900
Bolt and Heeres, The Spleen, 339
Bolton (H.), A New Blattoid Wing from the Harrow Hill Mine, Drybrook (Forest of Dean), 902
Bonacina (L. C. W.), Calendar Reform, 289; Climatic Continentality and Oceanity, 549
Bonde (C. von), The Heterosomata (flat-fishes) of South Africa, 796
Bone (Prof. W. A.), D. M. Newitt, and D. T. A. Townend, Gaseous Combustion at High Pressures. Pt. III., 622
Bonnevie (Prof. K.), The Work of the League of Nations Committee on Intellectual Co-operation, 829
Bonnier (Prof. G.), [obituary article], 264
Bordas (F.) and T. Touplain, The Denaturation of Ethyl Alcohol, 554; Specific Characters of the Heavy Oils of Beechwood Creosote, 763
Bordet (Prof. J.), Microbic Transmissible Autolysis, 339
Bordier (H.), The Influence of Diathermic d'Arsonvalisation on the Endocrinic Glands, 488
Born (Prof. Max), Der Aufbau der Materie: Drei Aufsätze über moderne Atomistik und Electronentheorie. Zweite Auflage, 109; traduit par H. Bellenot, La Constitution de la matière, 109; traduit par Dr. F. A. Finkelstein et J.-G. Verdier, La Théorie de la relativité d'Einstein et ses bases physiques: exposé élémentaire, 697
Boruttau (Prof. H.), [death], 888
Bosanquet (B.), [death], 230; [obituary article], 263
Bose (Prof. D. M.) and S. K. Ghosh, Tracks of α-Particles in Helium, 463
Bosworth (Dr. T. O.), with an Account of the Palæontology by H. Woods, Dr. T. W. Vaughan, Dr. J. A. Cushman, and others, Geology of the Tertiary and Quaternary Periods in the North-west Part of Peru, 527
Bouguer (P.), Essai d'optique sur la gradation de la lumière, 320
Boule (Prof. M.), avec la collaboration d'A. Thevenin, Mammifères fossiles de Tarija, 699
Boulenger (Dr. C. L.), appointed professor of zoology at Bedford College for Women, 723
Bourde (J.), Manuel des chemins de fer, 564
Bourguel (M.), The Preparation of True Acetylenic Hydrocarbons, 488
Bousfield (W. R.) and C. Elspeth Bousfield, Vapour Pressure and Density of Sodium Chloride Solutions, 622
Boussinesq (Prof. J.), Cours de physique mathématique de la Faculté des Sciences. Compléments au tome 3, 356
Bouzat (A.), A Class of Unstable Hydrates known as Hydrates of Gases, 243
Bower (Prof. F. O.), appointed chairman of the council of the Association of University Teachers of Scotland, 273; Comparative Embryology of Plants, 270; Relation of Size to the Elaboration of Form and Structure of the Vascular Tracts in Primitive Plants, 419; *Spiranthes Autumnalis*, 185
Bower (W. R.), The Position of Technical Education, 760
Bowman (Dr. A.), appointed superintendent of scientific investigations under the Fishery Board for Scotland, 782
Boys (Prof. C. V.), A Puzzle Paper Band, 774
Braak (Dr.), appointed director of the Royal Magnetical and Meteorological Observatory, Batavia, 29; Cloud Formation, 375
Bradford (E. J.), A Geography Test in Secondary Schools, 65
Bradford (Dr. S. C.), The Nature of Gels, 200
Bragg (Sir William), elected Fullerian professor of chemistry, and director of the Laboratory and of the Davy Faraday Research Laboratory of the Royal Institution, 783; Crystal Structure of Basic Beryllium Acetate, 532; New Methods of Crystal Analysis and their Bearing on Pure and Applied Science (Trueman Wood Lecture). Supplement (June 9), iii, and 781; The Nature of the Liquid State, 428

Brammall (A.) and H. F. Harwood, Dartmoor Occurrences of Rutile, Brookite, and Anatase; Zircon, 135; The Dartmoor Granite (Widecombe area), 486
Bramwell (J. C.), R. J. S. McDowall, and B. A. McSwiney, The Variation of Arterial Elasticity with Blood Pressure in Man, 274
Brandt (Prof. A.), Plea for the Compulsory Teaching of English in Germany, 518
Brauner (Prof. B.), elected an honorary fellow of the Chemical Society, 439; Transcription of Russian Proper Names, 290
Brazier (C. E.), Magnetic Measurements in Normandy, 588
Breeze (M. S. G.), Some Causes of Sterility in Solanaceous Plants due to Protozoa and Chytridiaceous Parasites, 866
Bréguet (A. L.), approaching centenary of the death of, 855
Brémond (P.), The Persistence of the Colour of the Ions in Ceramic Colours or Colouring Materials obtained at a High Temperature, 727
Brenans (P.) and C. Prost, The Iodosalicylic Acids, 903
Brentano (Dr. J. C. M.), appointed lecturer in physics in Manchester University, 240
Breton (J. L.), Spark-gaps in which the Spark in a Gaseous Dielectric is deflected by a Strong Air Current, 383
Brewster (G. W.), Common Sense of the Calculus, 837
Bride (Dr. T. M.), appointed chemical lecturer in ophthalmology in Manchester, 901
Bridgman (P. W.), The Compressibility of Metals at High Pressures, 208
Briggs (G. E.), re-appointed demonstrator in plant physiology in Cambridge University, 273
Briggs (H.) and J. Mallinson, Further Tests upon Metal Dewar Flasks intended to hold Liquid Air, 830
Bright (Sir Charles), Relations between the Empire's Telegraphs and Trade, 371
Brill (Dr. A. A.), Fundamental Conceptions of Psychoanalysis, 316
Brinkmann (Prof. A.), The New Marine Biological Research Station of the Bergen Museum, 358
Brinkmann (H. W.), On Riemann Spaces conformal to Euclidean Space, 554
Briquet (A.), The Invasion of the Sea on the Coast of Berck and the Teachings of Recent Geology, 275
Briquet (Dr. J. I.), elected a foreign member of the Linnean Society, 680
Brislee (Dr. F. J.), Instruction and Training in the Practical Use, etc., of the Modern Microscope, 239
British Drug Houses, Ltd., Chemical Catalogue. New issue, 197
Briton-Jones (H.), appointed lecturer in mycology at the Agricultural and Horticultural Station, Long Ashton, 273
Britton (N. L.) and J. N. Rose, The Cactaceae: Descriptions and Illustrations of Plants of the Cactus Family. Vol. 3, 426
Broad (Prof. C. D.), Scientific Thought, 872; Various Meanings of the Term "Unconscious," 587
Brochet (A.), The Hydrogenation and Dehydrogenation of Castor Oil and its Derivatives, 383
de Broglie (M.), Isotopes, 510; and E. Friedel, The Diffraction of the X-rays by Smectic Bodies, 487; and J. Cabrera, The Gamma Rays of the Radium and Thorium Family studied by their Photo-electric Effect, 275; and A. Lepape, The K Absorption Discontinuity of Krypton and Xenon, 903; and J. Cabrera, The K Absorption Spectrum of Element 72 (Celtium), 347
Broili and Schlosser, The Tooth of Hesperopithecus, 406
Brooke-Smith (Com. L. A.), Weather Forecasting in the North Atlantic and Home Waters for Seamen, 107
Brooks (C. E. P.), The Evolution of Climate, 561
Brooks (F. T.) and C. C. Hansford, Moulds on Meat in Cold Storage, 582
Brown (E.), Poultry Keeping on the Farm, 804
Brown (Dr. E. V.), Quaker Aspects of Truth, 145
Brown (Prof. E. W.), The Eighth Satellite of Jupiter, 546
Brown (Miss Ida), Hornblende and Bytownite from Hypersthene Gabbro, Black Bluff, near Broken Hill, 311
Brown (N. E.), The Cactus Family, 426
Brown (W.), Growth Rate and Cultural Factors of the same Species of Fusarium, 274
Brown (Dr. W.), Psychology and Criminal Responsibility, 581; Suggestion and Mental Analysis: an Outline of the Theory and Practice of Mind Cure. Third edition, 803
Brown (W. A.), The Problem of Classification in Religion, 134
Brown (W. E. L.), Adsorption and Hæmoglobin, 881
Browne (Rev. H. C.), A Simple Form of Photographic Depth Chart, 831
Browne (W. R.), Occurrence of Calcite in a Basalt from the Maitland District, N.S.W., 311; and W. A. Greig, An Olivine-bearing Quartz-monzonite from Kiandra, N.S.W., 311
Browning (Dr.), The Microscope in Leather-making, 239
Brownlie (D.), Boiler Plant Testing: a Criticism of the present Boiler Testing Codes and Suggestions for an Improved International Code, 215; Early History of the Gas Process, 512
Bruce (Sir David), the Albert Medal of the Royal Society of Arts awarded to, 854; the work of, 507
Bruce (the late Dr. W. S.), foundation of a memorial prize to, 854
Brühl (P.) and K. Biswas, A New Species of Cylindrospermum from Bengal, 555
Brunt (D.), A Double-Vertical-Reflection Mirage at Cape Wrath, 222; Waterspouts, 82; and J. Durward, Notes on Meteorological Corrections for the Use of Gunners, 107
Brunton (D. W.) and J. A. Davis, Modern Tunneling. (New Chapters on Railroad Tunneling, by J. V. Davies.) Second edition, 494
Brutzkuo (M.), The Theory of Internal Combustion Motors, 903
de Bruyn (Miss), The Saprophytic Life of Phytophthora in the Soil, 305
Bryan (Prof. G. H.), Recent Contributions to Aviation Problems, 886; The Definition of Limiting Equality, 183; The Phantom Island of Mentone, 430
Bryant (W. W.), [obituary article], 229
Bryce (Viscount), Memories of Travel, 770
Buchanan (Sir Walter), gift to Victoria College, Wellington, N.Z., 518
Budge (Sir E. Wallis), elected a foreign correspondent of the Lisbon Academy of Sciences, 855
Bugnon (P.), The Number of Cotyledons of Ficaria, 488
Bull (P. G.), Chemistry of To-day: the Mysteries of Chemistry lucidly explained in a Popular and Interesting Manner free from all Technicalities and Formulæ, 145
Bullen (G. E.), [obituary], 506
Buller (Prof. A. H. R.), Rea's "British Basidiomycetæ," 213
Burgess (Dr. G. K.), appointed director of the U.S. Bureau of Standards, 819
Burkill (J. C.), awarded a Smith's prize in Cambridge University, 417
Burkitt (A. N. St. G. H.) and Prof. J. I. Hunter, A Neanderthaloid Australian Skull, 198
Burkitt (M. C.), The Copper Age in Spain and Portugal, 563
Burne (Miss Charlotte Sophia), [obituary], 156
Burnham (T. H.), Special Steels: a Concise Treatise on the Constitution, Manufacture, Working, Heat Treatment, and Applications of Alloy Steels, for Students, Operators, and Users of Special Steels, chiefly founded on the Researches regarding Alloy Steels of Sir Robert Hadfield, 804

TITLE INDEX.

Aberdeen: Medical Officer of Health, resignation of Prof. M. Hay, 760; United Free Church College, Prof. J. A. Thomson to deliver the Thomson lecture at the, 133; University: W. W. M'Clelland appointed principal lecturer on education in the Edinburgh Training Centre; Prof. Bower appointed chairman of the Association of University Teachers of Scotland, 273; conferment of an honorary degree on the Duke of Richmond and Gordon; Prof. W. Mitchell appointed Gifford lecturer for 1924–25 and 1925–26, 345; building alterations in, 417; conferment of honorary degrees, 484; the bequest of Miss Anne Hamilton Cruickshank, 517; W. G. Mackinnon appointed assistant in geology, 552; Sir Robert Horne's Rectorial Address, 620; the Blackwell prize awarded to F. C. Diack; appointments, 864; proposed hospital development, 899

Aberration: and the Döppler Effect as treated in the Theory of Relativity, C. W. Hume, 623; Diffraction Effects, G. C. Steward, 418

Aboriginal Cylindro-conical Stones, G. Horne, 311

Absolute Measure and the C.G.S. Units, Sir George Greenhill, 259

Absorption: Bands, Wave-length Measurement of, The Coincidence Method for the, Dr. H. Hartridge, 205; Spectra and Atomic Structure, V. Henri, 859

Acetylene, The Action of, on Zinc Ethyl, J. F. Durand, 654

Acetylenic Hydrocarbons, The Preparation of True, M. Bourguel, 488

Acids, Removal of, from Solution, by Precipitates of Alumina, A. Charriou, 452

Acquired Characters, The Inheritance of, Prof. E. W. MacBride, 134; Breeding Experiments on, Dr. P. Kammerer, 637; J. T. Cunningham, 702

Actinium, The Relation of, to Uranium, Dr. A. S. Russell, 703

Actinograph, An Improved, Note on the Influence of a Glass Shade, A. W. Clayden, 727

Actuarial Mathematics, 769

Adaptation to Changes in Salinity, Intervention of the Spleen in the Phenomena of, F. Gueylard, 554

Adsorption and Hæmoglobin: Sir W. M. Bayliss, 666; W. E. L. Brown, 881; Prof. A. V. Hill, 843; J. Barcroft; N. K. Adam, 844; the Criteria of, The Combination between Oxygen and Hæmoglobin, and, N. K. Adam, 496

Aegilops, Chromosome Numbers in, Prof. J. Percival, 810

Aerial Surveying by Vertical Photographs, Recent Experiments in, Prof. B. Melvill Jones and Major J. C. Griffiths, 707, 745

Aerodynamics, Use of the Millibar in, Major A. R. Low, 535

Aeronautic Investigations, Recent, and the Aeroplane Industry, Prof. J. S. Ames, 363

Aeronautical: Maps, Projection for, Col. E. M. Jack and Capt. G. T. McCaw, 788; Research Committee, Report of the, 1922, 306

Aeroplane: The Low-power, or Aviette, Prof. L. Bairstow, 672; Cross-channel Flight, An, G. Barbot, 645; Flight in the U.S.A., A Long Non-Stop, Lieuts. Macready and Kelly, 645

Africa, Tropical, Pasture Grass in, T. M. Dawe, 198

African: Sign Writing, C. W. Hobley, 373; Woodland Formations, Aspects of, C. F. M. Swynnerton, 419

Agardh's, C. A., "Aphorismi botanici," Dr. B. Daydon Jackson, 309

Age and Area: a Study in Geographical Distribution and Origin of Species, Dr. J. C. Willis. With Chapters by H. de Vries, H. B. Guppy, Mrs. E. M. Reid, and Dr. J. Small, 39; and Natural Selection, J. T. Cunningham, 287; Hypothesis, The, J. Adams, 114; Dr. J. C. Willis, 115; in Biology, W. C. F. Newton, 48; in Natural Selection, Dr. H. L. Clark, 150

Age Distribution, Normal, Stability of the, A. J. Lotka, 36

Agricultural: Botany, National Institute of, Third Report of the Council of the, 478; Cyclopædia, A Great American, Sir John Russell, 140; problem, appointment of a tribunal of investigation into the, 24; Progress in India, D. R. Sethi and others, 584; Research and Education, grants for, 405; Science, Rothamsted and, Sir John Russell, 466; Scholarships, etc., to be awarded by the Ministry of Agriculture and Fisheries, 449

Agriculture in the Tropics, an Elementary Treatise, Dr. J. C. Willis. Third edition, 876

Air: at Great Heights, The Temperature of the, Prof. F. A. Lindemann and G. M. B. Dobson, 622; Conference, The Third, Prof. L. Bairstow, 238; The, and its Ways: the Rede Lecture (1921) in the University of Cambridge, with other contributions to Meteorology for Schools and Colleges, Sir Napier Shaw, 871; with Temperature, The Variation of the Specific Heat of, Prof. J. R. Partington and W. J. Shilling, 170

Alanine, Conversion of, into Pyruvic Acid by the Direct Action of Oxygen, L. J. Simon and L. Piaux, 727

Alaska, Fumaroles in, 269

Alcohol: in Commerce and Industry, C. Simmonds, 181; -Petrol Mixtures, The Stability of, in the Presence of Water, M. Aubert and G. Dixmier, 762

Alcohols: The Catalytic Dehydration of, by Dilute Sulphuric Acid, J. B. Senderens, 520; the Glucosides of, The Diastatic Hydrolysis of, H. Colin and Mlle. A. Chaudun, 347

Aldebaran, Projection of, on the Moon, R. L. Waterfield, 822

Algebraical Equations, The Grapho-mechanical Determinations of Systems of Real or Imaginary Solutions of, J. Roudaire-Miégeville, 310

Algerian Earthquake of August 25, 1922, The, Mme. A. Hee, 135

Alkali Polyhalides, Significance of the Experimentally Determined Crystal Structures of the, G. L. Clark, 868

Alkaloids, A New Reagent for, and the Preparation of the Iodostibinates of these Substances in the Crystallised State, M. Caille and E. Viel, 692

Allantoplacenta, The Phylogenetic Significance of the Marsupial, Prof. T. T. Flynn, 136

All-Electric Age, The, A. G. Whyte, 494

Allotropy, The Theory of, Prof. A. Smits, translated by Dr. J. S. Thomas, 733

Alloys: Extension of, in Course of Transformation, A Phenomenon observed during the, A. Portevin and F. Le Chatelier, 383; Resistant to Corrosion, Sir Robert Robertson and others, 619; The Inner Structure of, Dr. W. Rosenhain, 647; The Thermo-electric Power of, H. Pélabon, 762

Alpha: Particles in Gases, Some Interesting Tracks of, R. W. Ryan and W. D. Harkins, 114; -ray Tracks, Forked, Study of, P. M. S. Blackett, 381

Alphitonia excelsa Reiss, The Glucoside occurring in the Timber of the Red Ash, H. G. Smith and J. Read, 311

Alpine ABC, An, and List of Easy Rock Plants, arranged by A. Methuen, 216

Altitude, High, The Effect of, on the Physiological Processes of the Human Body, J. Barcroft, 134

Aluminium: and its Alloys, Lt.-Col. C. Grard, translated by C. M. Phillips and H. W. L. Phillips, 389; and other Metals, Single Crystals of, Prof. A. W. Porter, 362; Crystal, The Distortion of an, during a Tensile Test (Bakerian Lecture), G. I. Taylor and C. F. Elam, 309; On Some Alloys of (Light Alloys), Dr. W. Rosenhain, S. L. Archbutt, and Dr. D. Hanson, 389; Sub-group, The Series-Spectra of the, J. A. Carroll, 418; The Dilatometric Study of the Alloys of, with Magnesium and Silicon, A. Portevin and P. Chevenard, 275

Alveolar Air, Effect of Suspended Respiration on the Composition of, H. S. H. Wardlaw, 136

Alytes, Dr. Kammerer's, Dr. W. Bateson, 738

Amber and the Dammar of Living Bees, M. Stuart, 83

America: Research Departments in Manufacturing Firms in, Sir J. J. Thomson, 855; The National Research Council of, 31

American: Association Meeting at Boston, 482; Chemical Society, to issue two Series of Monographs, 680; Institute of Electrical Engineers, the Edison medal of the, awarded to Dr. R. A. Millikan, 266; Mycology, 28; Phytopathological Society, Fourth Annual Field Meeting of the, 714; schools and colleges, men and women students and teachers in, 168
Aminosäuren, Polypeptide und Proteine II. (1907–1919), Untersuchungen über, E. Fischer, herausgegeben von M. Bergmann, 768
Ammonia: The Spectrum of, W. B. Rimmer, 793; Thermodynamic Properties of, Tables of, 821
Ammonium: Sulphides, Thomas and Riding, 859; The Sulphide and Hydrosulphide of, J. S. Thomas, 796
Amphibian Colour Change, Studies on, H. R. Hewer, 450
Amundsen Expedition, The, 370
Anæsthetics, New General, 713
Anatomy, Practical, A Manual of, A Guide to the Dissection of the Human Body, Prof. T. Walmsley. In 3 parts. Part 3, 460
Andover District, The: an Account of Sheet 283 of the One-inch Ordnance Map (Small Sheet Series), O. G. S. Crawford, 701
Anemometer, A Compensated Hot Wire, Huguenard, Magnan, and A. Planiol, 275
Angiospermous Descent, The Strobilus Theory of, J. Parkin, 486
Animal: Nutrition: Foods and Feeding, E. T. Haloran, 804; Problems in the Field of, 854; Research in, 489; Studies in, 651; Organs: The Unit Activity of, Dr. V. R. Khanolkar, 304; Parasitology: Some Modern Developments in, Dr. Annie Porter, 162
Annual Register, The: a Review of Public Events at Home and Abroad for the Year 1922, edited by Dr. M. Epstein, 737
Antarctic: Crustacea, Some, Prof. W. M. Tattersall, 753; Geophysics, 897; Saga, An, Dr. H. R. Mill, 386
Anthracite and the Anthracite Industry, A. L. Summers, 78
Anthrax, Vaccination against Symptomatic, by Toxins, E. Leclainche and H. Vallée, 243
Anticyclones, The Cause of, R. M. Deeley, 83, 256, 634; Catherine O. Stevens, 150; Major A. H. R. Goldie, 429, 634; W. H. Dines, 495
Antimony-lead Alloys, Electric Potential of, S. D. Muzaffar, 382
Antipodean Flora, Dr. Alex Hill, 860
Antiquity, The Claim of, 407
Ants, Venom of, New Researches on the, R. Stumper, 275
Aqueous Solutions, Temperature of Maximum Density of, A. Taffel, 690
Arab Medicine and Surgery: a Study of the Healing Art in Algeria, M. W. Hilton-Simpson, 112
Arabian Alchemy and Chemistry, E. J. Holmyard and others, 300
Arabs: in the Sudan, A History of the, and Some Account of the People who preceded them and of the Tribes inhabiting Dárfúr, H. A. MacMichael, 2 vols., 176; of the Sudan, The, Prof. C. G. Seligman, 176
a-rays, Measuring Strong Ionisations due to the, Mlle. Irène Curie, 831
Arc Rectifier, An, L. Dunoyer and P. Toulon, 96
Archæological History, 454
Archaic Fishes, Palæontology and, Prof. J. Graham Kerr, 113
Architecture, The Future of, S. C. Ramsey, 268
Arctic: Lands, The Future of, Dr. H. R. Mill, 839; Seas, Distribution of Ice in, 411
Area of Distribution as a Measure of Evolutionary Age, Dr. W. Bateson, 39
Aristotelian Society, Proceedings of the, New Series, vol. 22, 45
Arizona: New Fossil Turtle from, C. W. Gilmore, 754; Pliocene Vertebrates from the Tertiaries of, J. W. Gidley, 443
Armaments, Science and, Dr. L. C. Martin, 82, 429; Dr. J. Weir French, 186
Armstrong College, anonymous gift to; impending erection of a permanent library, 723; bequest to, by C. T. Milburn, 133
Army Medical Service, Maj.-Gen. Sir William B. Leishman appointed Director-General of the, 301
Arsenic, Estimating, Methods of, A. Chaston Chapman and others, 196
d'Arsonvalisation, The Influence of Diathermic, on the Endocrinic Glands, H. Bordier, 488
Arterial Elasticity, The Variation of, with Blood Pressure in Man, J. C. Bramwell, R. J. S. McDowall, and B. A. McSwiney, 274
Artesian Water in Australia, 583
Arts, Royal Society of, award of the Albert medal to Sir David Bruce and Sir Ronald Ross, 854
Aryl Formamides, The Decomposition of the, A. Mailhe, 452
Aryldialkylglycols, The: a New Series of Hypnotics, M. Tiffeneau and H. Dorlencourt, 763
Asiatic Society of Bengal, election of Officers and Council of the, 408
Assam, Frontier Tribes of, 282
Aster tripolium on Salt Marshes, H. W. Chapman, 256
Asteroids, Families of, K. Hirayama, 822
Astrolabe, Prismatic, designed and made at the Admiralty Research Laboratory, Teddington, T. Y. Baker, 346
Astronomical: Circulars, 197; Interferometry, Prof. Michelson's work in, Prof. Eddington, 240; Society of the Pacific, The gold medal of the, presented to B. Baillaud, 337; Union, The International, 101

ASTRONOMICAL NOTES.

Comets:
Baade's Comet, Dr. W. H. Steavenson, 27; A New Comet, W. N. Abbot, 857
Meteors:
The January Meteors, 60; Fireballs in February, W. F. Denning, 197; Great Fireball in Northern India on December 28, 1922, W. F. Denning, 372; Meteors in April, 441; Meteors of March 17, W. F. Denning, 479; A Supposed Meteorite at Quetta, 510; The April Meteor Shower, W. F. Denning, 646; Temperature and Density of the Upper Atmosphere deduced from Meteors, Prof. F. A. Lindemann and C. M. Dobson, 646; May Meteors, 682; June Meteoric Displays, W. F. Denning, 785
Observatories:
Annuaire de l'Observatoire Royal de Belgique, 1924, 752; Stonyhurst College Observatory, Report for 1922, 822; Proposed Solar Observatory in Australia, 857
Planets:
New Observations of Jupiter, F. Sargent, 27; Mercury, 60; Lost Planet Recovered, 159; The Great Red Spot on Jupiter, W. F. Denning, 233; Partial Eclipse of the Moon, 301; The Atmosphere of Venus, Prof. St. John and G. B. Nicholson, 301; Vesta, Mr. Bawtree, 479; Planetary Radiation, W. W. Coblentz, 510; The Eighth Satellite of Jupiter, Prof. E. W. Brown, 546; Jupiter, F. Sargent, 580; The Present Condition of the Giant Planets, Dr. H. Jeffreys, 615; Irregularities in the Moon's Motion, W. Child, 682; The Theory of Jupiter's Satellites, Prof. de Sitter, 717; The Diameters of Saturn's Satellites, Major P. H. Hepburn, 752; Families of Asteroids, K. Hirayama, 822; Photometric Observations of the Planet Mercury, J. Hopmann, 857
Stars:
Interferometer Measures of Double Stars, Dr. P. W. Merrill, 27; Parallaxes of Fifty Stars; Variable Star Maxima and Minima for 1923, Dr. L. Campbell, 94; Occultations of Stars by the Moon, 128; Spectroscopic Parallaxes of A-type Stars, Adams and Joy, 128; The Radial Motions of Stars of Type N, J. H. Moore, 301; Increase of Brightness of Beta Ceti, 338; The Spectra of Visual Double Stars, F. C. Leonard, 338; Stellar Spectra of Class S, P. W. Merrill, 372; Problems of the Nebulæ, Rev. H. Macpherson, 441; The Brightness of Beta Ceti, 479; Spectra of Three O-type Stars, Dr. H. H. Plaskett, 580; Nature of the Spiral Nebulæ, Prof. Lindemann, 615; Variable with a Remarkable Spectrum, Dr. H. Shapley, 615; Unknown Lines in Stellar Spectra, F. E. Baxandall, 717; 850 New Nebulæ, Dr. H.

Shapley, 717; Projection of Aldebaran on the Moon, R. L. Waterfield, 822; Photographic Studies of Nebulæ, J. C. Duncan, 857; Variations in the Spectrum of θ^2 Orionis, F. Henroteau, 892; Colours and Spectra of Double Stars, F. C. Leonard, 892; The Radial Velocities of 1013 Stars, W. S. Adams and A. H. Joy, 892

Sun:

Solar Prominence Activity, 27; Coming Solar Eclipses, 60; Observations at Wallal of the Eclipse of September 1922, J. Hargreaves and G. S. Clark-Maxwell, 128; The Position of the Solar Apex, J. S. Paraskevopoulos, 159; The Eclipse of September 1922 in Queensland, J. C. Russell, 441; Solar Eclipse Investigations, Prof. A. D. Ross, 510; The Corona of 1908 and Solar Prominences, J. Evershed, 785

Miscellaneous:

British Astronomical Association Handbook for 1923, 27; Atmospheric Dispersion in Parallax Work, W. M. H. Greaves and C. Davidson, 27; The Drayson Paradox, A. H. Barley, 94; Calendar Reform, Rev. D. R. Fotheringham, 159; Astronomical Circulars, 197; Periodic Motion in the Three-body Problem, Prof. Strömgren, 233; The Zodiacal Light, W. F. Denning, 338; Old Egyptian Water-clocks, 479; Greece adopts the Gregorian Calendar, 546; Astronomy in the United States, 546; The Astronomical Society of South Africa, 717

Astronomy: and Geology, The Borderland of, Prof. A. S. Eddington, 18; General, H. Spencer Jones, 247; in the United States, 546; Outlines of, 247; The Interferometer in, Prof. A. S. Eddington, 572; The Rôle of, in the Development of Science, Dr. M. A. Peres, 162

Athenæum Club: Maj.-Gen. Sir Frederick B. Maurice, Dr. A. Scott and Prof. A. N. Whitehead elected members of the, 232; Dr. H. H. Dale, Rev. Prof. G. Milligan and Very Rev. Dean W. F. Norris elected members of the, 544; Prof. H. Lamb, Lord Meston, and G. Gilbert Scott elected members of the, 406

Atlas, Orographical, Regional, Economic, edited by T. Franklin. Part 4: Africa, 494

Atmosphere: A Heavier Constituent of the, A Critical Search for a, by means of the Mass-spectrograph, Dr. F. W. Aston, 689; Characteristics of the, up to 200 km., as obtained from observations of Meteors, G. M. B. Dobson, 487; The Water in the, Dr. G. C. Simpson, Supplement (April 14), v.; Upper Layers of the, Constitution of the, L. Vegard, 831; Vertical Movements of the, I. I. Kassatkine, 787

Atmospheric: Dispersion in Parallax Work, W. M. H. Greaves and C. Davidson, 27; Humidity in the United States, Prof. R. de C. Ward, 511

Atmospherics: R. M. Deeley, 362; The Nature of, R. A. Watson Watt and E. V. Appleton, 622; The Study of, F. Baldet, 554; Radiotelegraphic, in relation to Meteorology, C. J. P. Cave and R. A. W. Watt, 34

Atom? A Static or Dynamic, Dr. N. R. Campbell, 569; The Structure of the, Hon. B. Russell, 477; R. H. Fowler, 523

Atomic: Form: with special reference to the Configuration of the Carbon Atom, E. E. Price, 733; Number 72, On the Missing Element of, Dr. D. Coster and Prof. G. Hevesy, 79; Dr. A. Scott, 195; Number 72, On the Element of, Profs. G. Urbain and A. Dauvillier, 218; Radii, Constant, The Hypothesis of, R. W. G. Wyckoff, 555

Atoms and Isotopes, The Evolution of, W. D. Verschoyle, 12

Aucuba Leaves preserved in a Vacuum, The Vitality of, P. A. and P. Dangeard, 171

Audition, The Mechanism of, F. W. Kranz, 291

Aurora: and Allied Phenomena, Dr. C. Chree, 135; Borealis: of March 22-23, 1920, Photogrammetric Measurements of the, Prof. C. Störmer, 171; The Spectrum of the, and the Upper Layers of the Atmosphere, L. Vegard, 587

Auroræ, Recent, W. B. Housman, 706

Austral Rhynchonellacea of the "Nigricans Series" with a Description of the New Genus Tegulorhynchia, F. Chapman and I. Crespin, 311

Australasian Biological Collecting Expedition, An, 272

Australia: proposed Solar Observatory in, 857; The Natives of, S. H. Ray, 121; Western, University of, Government grant for the Permanent Buildings of the, 518

Australian: Anthicidæ (Coleoptera), A. M. Lea, 136; Ethnological Collection, Guide to the, exhibited in the National Museum of Victoria, Sir Baldwin Spencer, Third edition, 121; National Research Council: publication of a Quarterly Journal of the, 440; Sir David Orme Masson elected president of the; work of the, 478; Skull, An Ancient, A. N. St. G. H. Burkitt and Prof. J. I. Hunter, 198; Tipulidæ, New or Little-known Species of, (Diptera), Pt. I., C. P. Alexander, 136; Trees, Chemical Characteristics of, H. G. Smith, 649

Auto-oxidation and Anti-oxygenic Action, C. Moureu and C. Dufraisse, 519

Aviation Problems, Recent Contributions to, Prof. G. H. Bryan, 886

Ayrshire Bauxitic Clay, The, G. V. Wilson, 110

Baade's Comet, Dr. W. H. Steavenson, 27

Baby: Clinic Statistics, Miss M. N. Karn and Prof. Karl Pearson, 547; Week, National, 890

Babylonians, Ancient, A Biochemical Discovery of the, L. J. Harris, 326

"Baccy-juice," The so-called, in the Waters of the Thames Oyster-beds, Dr. J. H. Orton, 773

Bacillaria paradoxa, Distribution of the Organ-Pipe Diatom, F. Chapman, 15

Bacot, A. W., proposed memorial of the late, 749

Bacteria and Travertine, J. Parry, 269

Bacterial Count Work, A New Culture Medium for, H. G. Thornton, 411

Bacterio-stasis, Selective, The Mechanism of, J. W. Churchman, 763

Badger: The, Afield and Underground, H. M. Batten, 800

Bakerian Lecture, The, G. I. Taylor and C. F. Elam, 309

Bakhuis-Roozeboom medal, the, conferred on Prof. G. Tammann, 612

Balfour, Sir Isaac Bayley, Prof. T. D. A. Cockerell, 150

Balkan Embroidery Patterns, Miss Edith Durham, 786

Ball Hardness and Scleroscope Hardness, H. O'Neill, 430

Ballot, Buys, medal, awarded to Sir Napier Shaw, 91

Balmer Series Lines of High Frequency, Photography of, Prof. R. Whiddington, 636

Baluchitherium osborni (? syn. *Indricotherium turgaicum*, Borrissyak), C. F. Cooper, 134

Barometric Depression and Anaphylactic Shock, A. Lumière and H. Couturier, 655

Batavia, Royal Magnetical and Meteorological Observatory, retirement of Dr. W. van Bemmelen; appointment of Dr. Braak, 29

Batrachians, The Inhibiting Action of the Internal Medium of, on the Fecundation and the Parthenogenetic Activation of their Eggs, A. Weber, 728

Batteries with Fluorescent Liquid, A. Grumbach, 171

Bauxite in Ayrshire, 110

β Ceti, Increase of Brightness of, C. Flammarion, 451

Bedde Group of Tribes of Northern Nigeria, The, F. W. H. Migeod, 170

Bee-keeping, Pamphlet on, 509

Beetles, More, J. H. Fabre. Translated by A. Teixeira de Mattos, 285

Belfast, Queen's University: the bequest of H. Musgrave; R. C. Johnson appointed lecturer in physics; S. P. Mercer appointed lecturer in agricultural botany and plant diseases, 380; resignation of Rev. Dr. T. Hamilton, 586

Belgian Botany: a Record of War Time, Prof. J. Massart, 97

Belgique, l'Observatoire Royal de, Annuaire de, 1924, 752

Belgium, grants to Universities in, 761

Benzene: Chloride, Vapour of, The Ultra-violet Absorption Spectrum of the, V. Henri, 762; Nucleus, Substitution in the, R. Fraser and J. E. Humphries, 512; Structure of, Dr. M. L. Huggins, 444

Benzoic Acid, The Ultra-violet Absorption Spectra of, and of the Three Oxybenzoic Acids, A. Castille and F. W. Klingstedt, 488
Bergen Museum, The New Marine Biological Research Station of the, Prof. A. Brinkmann, 358
Berkeley and Broome, J. Ramsbottom, 274, 553
Beryllium Acetate, Basic, Crystal Structure of, Sir W. H. Bragg, 532; Dr. N. V. Sidgwick, 808
Bessel Functions: A Treatise on, and their Applications to Physics, Prof. A. Gray and G. B. Mathews. Second edition prepared by A. Gray and Dr. T. M. MacRobert, 422; A Treatise on the Theory of, Prof. G. N. Watson, 422
Beta Ceti: Increase of Brightness of, 338; The Brightening of, E. O. Tancock, 479
Big Game, The Wonderland of, Major A. R. Dugmore, 782
Binary Organic Mixtures, the Cryoscopic Study of, N. Perrakis, 691
Bio-Chemistry, A Laboratory Handbook of, P. C. Raiment and G. L. Peskett, 181
Biodynamik, Grundlagen einer, Prof. J. Reinke, 72
Biological Action of Light, The Influence of Temperature on the, Dr. L. Hill and A. Eidinow, 653
Biologischen Arbeitsmethoden, Handbuch der, Herausgegeben von Prof. E. Abderhalden. Abt. V. Teil 3A, Heft 3, Lief. 69. Abt. IX. Teil 1, Heft 2, Lief. 71, 390; Abt. IX. Teil 4, Heft 1, Lief. 76, 530
Biology: in Utopia, 591; Religion and, E. E. Unwin, 531
Biometry and Genetics, Prof. R. Pearl and others, 513
"Bird Men" and Kindred Customs in the Balkans, Miss M. Edith Durham, 450
Birds: the Orientation Faculty of, Terrestrial Magnetism and, 711; (Second edition), C. S. Baker's, in the "Fauna of British India," H. C. Robinson and C. B. Kloss, 656; Soaring Flight and the "Olfactory" Organs of Birds, Prof. W. E. M'Kechnie, 48
Birmingham University: Appointments in, 167; Gift to, by the Mitsui Family; F. W. M. Lamb appointed assistant lecturer in pathology; appeal for funds, 240; Dr. H. H. Sampson appointed honorary assistant curator of the surgical section of the Pathological Museum, and J. S. M. Connell honorary assistant curator of the gynæcological section, 723; Bequests by Elizabeth Kenway and J. S. Taylor, 792
Birthday Honours, The King's, 783
Bismuthamines, The, a New Class of Bodies, A. C. Vournazos, 867
Bivalve Molluscs injuring Brickwork in the Calcutta Docks, Dr. N. Annandale, 555
Black: Currant, "Big Bud" of, 719; Maketu Sand, Constitution of, Dr. C. J. Smithells and F. S. Goucher, 397; Dr. A. Scott, 463
Blattoid Wing, a New, from the Harrow Hill Mine, Drybrook (Forest of Dean), H. Bolton, 902
Boat to travel against the Wind, a, 60
Boiler Plant Testing: a Criticism of the present Boiler Testing Codes and Suggestions for an Improved International Code, D. Brownlie, 215
Bone Harpoons discovered in Yorkshire, 547
Bones, Destructive Distillation of, E. V. Aleksejevski, 684
Boron, Valency of, Prof. J. Böeseken, 894
Borough Polytechnic, The Work of the, Sir Douglas McGarel Hogg, 241
Botanic Illustration, History of, during Four Centuries (Colour), Dr. B. Daydon Jackson, 623
Botanical Survey of British Malaya, The, 6
Botany in India, 547
Botulism: and Food Preservation (The Loch Maree Tragedy), Dr. G. Leighton, 737; in Scotland, Dr. G. R. Leighton, 415; Organism, Distribution of the, Prof. K. F. Meyer and others, 95
Bournemouth, Middle Eocene Flora of, The Cuticular Structure of certain Dicotyledonous and Coniferous Leaves from the, Miss Helena Bandulska, 206
Bowmore-Portaskaig District of Islay, Structure of the, J. F. N. Green, 725
Boys and Girls respectively in Secondary Schools, Report of the Consultative Committee on Differentiation of the Curriculum for, 657
Brain-workers, Payment for, 405
Brass-casting in the Central Cameroon, L. W. G. Malcolm, 129
Breeding Experiments on the Inheritance of Acquired Characters, Dr. P. Kammerer, 637; J. T. Cunningham, 702
Bristol University: H. Briton-Jones appointed lecturer in mycology, E. Ballard adviser in plant pathology, and H. P. Hutchinson organiser of research in willow growing at the Agricultural and Horticultural Station at Long Ashton, 273; War Memorial Tablet, 306; Dr. L. J. Russell appointed professor of philosophy, 449; The Promotion of Research in the, 790
British: Association: Committee on Training in Citizenship, Third Report of the, 307; meeting at Liverpool, Presidents and Recorders of the Sections, 91, 825; The Local Handbook of the, T. Sheppard, 16; Astronomical Association Handbook for 1923, 27; Basidiomycetæ: A Handbook to the Larger British Fungi, C. Rea, 213; Botany: Manual of, containing the Flowering Plants and Ferns arranged according to the Natural Orders, C. C. Babington. Tenth edition, edited by A. J. Wilmott, 251; Coleoptera, Records of, J. C. F. and H. F. Fryer, 683; Dyestuffs Corporation, Ltd., list of the products of the, 158; Empire: Exhibition, 1924, 37, 93; and a Scientific Exhibit, 715; Water-Power in the, T. Stevens, 607; Journal Photographic Almanac and Photographer's Daily Companion, 1923. Edited by G. E. Brown, 45; Meteorological and Magnetic Year Book, 1920. Part III. Section 2. Geophysical Journal, 1920, 45; Museum: (Natural History), addition of Dinosaurian remains to the, 231; protest against rumoured reduction of grant for, 265; (Natural History), Carboniferous Corals in the Geological Department of the, 371; The proposal to charge for admission to the, 405; (Natural History), the palæo-botanical Collection of Dr. D. H. Scott acquired by the, 406; (Natural History), Scientific Reunion of the Staff Association of the, 407; withdrawal of the proposal to charge for admission to the, 439, 475; (Natural History), a Rib of the *Cetiosaurus leedsi* added to the, 509; Guide to the Maudslay Collection of Maya Sculptures (Casts and Originals) from Central America, 631; (Natural History), acceptance of a portrait of Dr. A. Russel Wallace, 819; Mycological Society, Transactions of the. Vol. 8, Pts. 1 and 2, 234; Non-Ferrous Metals Research Association, Lectures on the Work of the, 406; North Borneo: An account of its History, Resources, and Native Tribes, O. Rutter, 391; The Natives of, E. O. Rutter, 309; Science Guild: Journal of the, February, 408; meeting at the Mansion House, 342; Work of the, 782; Surveying Instruments, W. H. Connell, 648; (*Terra Nova*) Antarctic Expedition, 1910–1913. Observations on the Aurora, C. S. Wright, 897; Determinations of Gravity, C. S. Wright, 898; University Statistics, 1921–22, 899; Upper Air Data in the Light of the Norwegian Theory of the Structure of the Cyclone, An Examination of, W. H. and L. H. G. Dines, 587
Broadcasting: a Picture, Dr. Fournier d'Albe, 751; appointment of a committee on, 613; and Wireless Sciences, 589; Pictures, A Method of, Dr. E. E. Fournier d'Albe, 811; Practical, Mr. Shaughnessy, 679; Transmitter, Sir Oliver Lodge, 13
Bronze Age, The, and the Celtic World, H. Peake, 454
Brown Bast Disease of Rubber Trees, A. Sharples, 234
Bubonic Plague, Surg.-Gen. Bannerman, 197
Building: Construction Research, 415; in Cob and Pisé de Terre, 415
Burettes, Notes on, V. Stott, 830
Burma: Eocene Pelecypoda of, Dr. G. de P. Cotter, 893; Riverine Tract of, Preliminary Note on the Ecology of Part of the, Dr. L. D. Stamp and L. Lord, 555
Butter-Making, Principles and Practice of, Dr. G. L. McKay and Prof. C. Larsen. Third edition, 77

"Cabinet du Roi," The, and the Forgotten Discoveries of Rochon, G. Bigourdan, 310
Cactaceæ, The: Descriptions and Illustrations of Plants of the Cactus Family, N. L. Britton and J. N. Rose, Vol. 3, 426

Cactus Family, The, N. E. Brown, 426
Caesium and other Alkali Elements, The Fluorescence and Channelled Absorption Spectra of, Prof. J. C. McLennan and D. S. Ainslie, 419
Calamintha, British Species of, and a Species new to this Country, H. W. Pugsley, 67
Calcite: certain remarkable Reticular Planes of, Reflection of Röntgen Rays on, C. Mauguin, 763; The occurrence of, in a Basalt from the Maitland District, N.S.W., W. R. Browne, 311
Calculus: and Probability for Actuarial Students, A. Henry, 769; Common Sense of the, G. W. Brewster, 837; Integral, A Treatise on the, with Applications, Examples, and Problems, J. Edwards. Vol. 2, 391; The Teaching of the, 837
Calcutta School of Tropical Medicine and Hygiene, The, 550
Calendar Reform: L. C. W. Bonacina, 289; Rev. D. R. Fotheringham, 159; Dr. C. F. Marvin's proposed, E. Gold, 309; in Greece, D. Eginitis, 487
California Institute of Technology, Gift to, by A. H. Fleming, 477
Cambridge University: Annual Report of the General Board of Studies, 102; offer by Sir Alfred Yarrow to found a studentship and a lectureship in Assyriology, 167; offer from the Development Commissioners to provide for a chair of animal pathology; proposal to confer an honorary degree on H. Gilbert-Carter, 204; Botanic Garden, Guide to the, H. Gilbert-Carter, 216; J. B. S. Haldane appointed Dunn reader in biochemistry; Dr. A. Hutchinson appointed University lecturer in crystallography; Dr. C. Shearer appointed University lecturer in embryology, 240; G. E. Briggs reappointed demonstrator in plant physiology; report of Syndicate on the admission of women to degrees; revised regulations for the medical examination, 273; foundation of a professorship of animal pathology, 306; women admitted as research students, 345; award of the Adams prize to J. Proudman; thanks of the First Lord of the Admiralty for service to the Navy; M. B. R. Swann elected fellow and lecturer at Gonville and Caius College, 380; proposed subject of Adams prize for 1923–24; Report of the Board of Research Studies; grants from the Gordon Wigan fund made to Prof. Punnett, Prof. Gardiner, Dr. A. Harker, and to Prof. Seward, 417; award of Rayleigh prizes to E. F. Collingwood, W. R. Dean, E. C. Francis, C. G. F. James, and M. H. A. Newman, 417; T. M. Cherry elected an Isaac Newton student; renewal of Isaac Newton studentship to M. H. Greaves; award of Smith's prizes to J. C. Burkill and A. C. Ingham, 417; The Duke of Devonshire elected High Steward; G. S. Adair, M. S. Blackett, and B. Ord elected fellows of King's College, 449; A Bill for the appointment of Statutory Commissioners, 517; Dr. G. S. Graham Smith appointed reader in preventive medicine; Dr. J. T. MacCurdy University lecturer in psychopathology; J. Mills elected to the Nita King research scholarship in the etiology, pathology, and prevention of fevers, 518; proposed conferment of honorary degrees, 620, 688; Dr. E. Lloyd Jones re-elected demonstrator of medicine; an honorary degree to be conferred on Dr. J. T. MacCurdy, 723; proposed honorary degrees; J. E. Littlewood re-appointed Cayley lecturer in mathematics; R. A. Herman re-appointed University lecturer in mathematics; J. Gray re-elected Balfour student; special grant to the Marine Biological Station at Plymouth, 792; H. M. Fox appointed demonstrator of comparative anatomy; appointments at the Solar Physics Observatory; proposed erection of a building for work in geodesy and geodynamics; Prof. N. Bohr to be nominated as an honorary member of the Philosophical Society, 828; appointments, 864; appointments; conferment of honorary degrees, 900
Camera Club, The Journal of the, 267
Camphor, Derivatives of, Absorption in the Ultra-Violet of a Series of, A. Haller and R. Lucas, 171
Canada, Higher Education in Eastern, Dr. Learned and President Sills, 66
Canary Islands: The, Their History, Natural History, and Scenery: an Account of an Ornithologist's Camping Trip in the Archipelago, D. A. Bannerman, 77
Cancer in Plants, W. Robinson and H. Walkden, 858
Cane-sugar Solutions, The Vapour Pressures of Concentrated, E. P. Perman and H. L. Saunders, 761
Cannel Coal, Lignite, and Mineral Oil in Scotland, 374
Capita Zoologica, 545
Carbon and Hydrogen: The Determination of, by the use of a mixture of Sulphuric Acid and Silver Bichromate, L. J. Simon and A. J. Guillaumin, 655; Arc Spectrum in the Extreme Ultra-Violet, The, F. Simeon, 205; Assimilation in Plants, Prof. D. Thoday, 162; Dioxide: Output of Aquatic Animals, A Method of Measuring the, J. T. Saunders, 243; Velocity of Absorption of, by Ammoniacal Solutions, P. Riou, 451; in Arable Soil, The Determination of, L. J. Simon, 796; Monoxide and Nitrogen. Structure of, Prof. H. Nagaoka, 859
Carboniferous Strata in County Sligo, Displacement of, A. E. Clark, 654
Carnegie: Institution of Washington, Department of Terrestrial Magnetism of the, Report of the, 542; Research Stations, Botany at the, 754; Trust for the Universities of Scotland, Annual Meeting of the, 518; United Kingdom Trust, The, Report for 1922, 621
Carotin-like Colours in Plant and Animal Tissues, 318
Carotinoids and Related Pigments: the Chromolipoids, Prof. L. S. Palmer, 318
Carpets: Archæology and Technology of, Dr. C. Singer, 71; Hand-woven, Oriental and European, A. F. Kendrick and C. E. C. Tattersall. 2 vols., 71
Carthage, Ancient, Excavations at, 581
Cass, Sir John, Technical Institute, The Work of the, Rev. J. F. Marr, 241
Cassava Plants, Growth of, T. G. Mason, 374
Castor Oil, The Catalytic Decomposition of, A. Mailhe, 135
Catalysis: and Steric Hindrance, G. Vawon and A. Husson, 654; Contact, Prof. Bancroft, 236; with special reference to New Theories of Chemical Action: A General Discussion held by the Faraday Society, 733
Catalytic Actions at Solid Surfaces, A Study of, X., Drs. E. F. Armstrong and T. P. Hilditch, 168; XI., 793
Catechin, Constitution of, Pt. I., J. J. Drumm, 831
Cathode Ray Oscillograph: The, A. B. Wood, 34; A Low-voltage, R. Webb, 34
Cathode Rays, The Passage of, through Matter, Schönland, 623, 866
Catholic Christians of Eastern Bengal, The, H. E. Stapleton, 373
Cattle, Significance of an Archondroplasia-like Condition met with in, F. A. E. Crew, 829
Cauliflower, The Morphological Nature of the Head of the, H. Coupin, 692
Causes and Consequences, Sir Bampfylde Fuller, 665
Cellulose: Acetate, The Elasticity of Organogels of, E. W. J. Mardles, 761; Fibres and Fabrics, The Destruction of, by Micro-Organisms and the Importance of the Microscope in the Study of this Destruction, A. C. Thayson and H. J. Bunker, 486; Researches on, C. F. Cross and C. Dorée, IV. (1910–1921), 12; Structure, The Determiners of, as seen in the Cell Walls of Cotton Hairs, Dr. W. L. Balls, 653
Celtium: and Hafnium, On, Dr. D. Coster and Prof. G. Hervey, 462; Element of Atomic Number 72, G. Urbain, 383; (Element 72), The Coexistence of, and the Yttria Earths, G. Urbain and A. Dauvillier, 451; Lines, On Urbain's, H. M. Hansen and S. Werner, 461
Cements and Artificial Stone: a Descriptive Catalogue of the Specimens in the Sedgwick Museum, Cambridge, the late J. Watson. Edited by Dr. R. H. Rastall, 803
Ceramic: Colours or Colouring Materials, Persistence of the Colour of the Ions in, obtained at a High Temperature, P. Brémond, 727; Industries, Applications of Physics to the, Dr. J. W. Mellor, 757
Cercariæ from Indian Fresh-water Molluscs, Major R. B. S. Sewell, 160
Chaffinch, Peculiar Habit of a, Sir David Wilson-Barker, 821
Chambers's Encyclopædia: a Dictionary of Universal Knowledge. New edition, edited by Dr. D. Patrick and W. Geddie. Vol. I., 597

Chaparral Scrub in California, W. S. Cooper, 268
Charred Documents, Deciphering, R. Davis, 160
Chemical: and Physical Tables, 493; Analysis, Quantitative, A Text-book of, Dr. A. C. Cumming and Dr. S. A. Kay. Fourth edition, 321; Characteristics of Australian Trees, H. G. Smith, 649; Elements, A Relation between the Atomic Numbers and Atomic Weights of the, F. Loewinson-Lessing, 275; Sense, The, 629; Society, Prof. W. P. Wynne nominated as president of the, 125; election of officers and council of the, 440; Prof. B. Brauner, Prof. E. Cohen, Prof. G. N. Lewis, Prof. C. Moureu, Prof. A. Pictet, and Prof. T. Svedberg elected honorary fellows of the, 439; Standards, Preparation and use of, Ridsdale and Co., 544; Symbols and Formulæ, Sir James Walker, 883; Technology and Analysis of Oils, Fats, and Waxes, Dr. J. Lewkowitsch. Sixth edition, entirely revised by G. H. Warburton. (In 3 vols.) Vol. 3, 595; Thermometers, Catalogue of, Pastorelli and Rapkin, Ltd., 545
Chemins de fer, Manuel des, J. Bourde, 564
"Chemist," The Term, A. Chaston Chapman, 405
Chemistry: and its Uses, A Text-Book for Secondary Schools, W. McPherson and W. E. Henderson, 78; Colloid, Laboratory Manual of, Prof. H. N. Holmes, 733; Colloid, of the Proteins, Prof. W. Pauli. Translated by P. C. L. Thorne. Part I., 733; for Beginners and Schools (with Glossary), C. T. Kingzett. Fourth edition, 78; History of, Dr. F. P. Venable, 392; in Industry, A. Chaston Chapman, 379; in Medieval Islam, E. J. Holmyard, 718; Inorganic, An, Prof. H. G. Denham, 180; Inorganic, A Text-book for Schools, E. J. Holmyard, 460; of Dental Materials, The, Prof. C. S. Gibson, 427; of Plant Products, An Introduction to the, Dr. P. Haas and T. G. Hill. Vol. 2, 283; of To-day: The Mysteries of Chemistry lucidly explained in a Popular and Interesting Manner free from all Technicalities and Formulæ, P. G. Bull, 145; Organic, Prof. W. H. Perkin and Prof. F. S. Kipping. New edition, Part I., 142; Organic, Elementary, W. H. Barrett, 321; Physical, Laboratory Manual of, Profs. A. W. Davison and H. S. van Klooster, 665; Physical, Lecture Demonstrations in, Dr. S. van Klooster, 251; Pure and Applied, International Union for, Conference at Cambridge, 825; Second Year College Chemistry: a Manual of Laboratory Exercises, Prof. W. H. Chapin, 285; Smith's Intermediate, revised and rewritten by Prof. J. Kendall and E. E. Slosson, 356; Tangle Unravelled: The, being Chemistry systematised on a New Plan based on the Works of Abegg, Kossel, and Langmuir, Dr. F. W. Gray, 770; Technical, at the University of Edinburgh, 826; Theoretical, Outlines of, Prof. F. H. Getman. Third edition, 701
Children: Difficult and Delinquent, Dr. R. G. Gordon, 718; Diseases of, Practical Handbook on the, for the Use of Practitioners and Senior Students, Dr. B. Myers, 531
Chili: Nitrate Deposits of, Origin of the, J. Stoklasa, 867; To-day and To-morrow, L. E. Elliott, 566
Chilian Earthquake of November 11, 24
Chilka Lake, The Fauna of an Island in the, Dr. N. Annandale, 378
Chimica generale ed applicata all' Industria, Trattato di, Prof. E. Molinari. Vol. 2: Chimica organica. Parte seconda: Terza edizione, 142
Chimie inorganique, Cours de, Prof. F. Swarts. Trois. édition, 701
China: Palæontological Research in, J. G. Andersson and others, 160; South-western, Chinese Tibet, and Northern Burma, return of K. Ward from, 231
Chlorine in the Ultra-violet, The Line Spectrum of, W. Jevons, 206
Chlorite-rock, A Peculiar, at Ible, Derbyshire, C. S. Garnett, 486
Chloroplasts and Cells, Prof. R. R. Gates, 635
Chœtoceros and Allied Genera, Living and Fossil, Sir Nicholas Yermoloff, 242
Cholera, The Evolution of the Copulatory Apparatus in the Genus, R. Jeannal, 655
Ciliary Movement, The Mechanism of, III., J. Gray, 450
Cinema, The, and Agriculture in the United States, 126
Cinnamic and Phenyl-propiolic Acids, Rate of Hydrogenation of, Dr. E. K. Rideal, 690
Circle of Scientific, Technical, and Trade Journalists, Sir Richard Gregory elected chairman of the, 94
Cirrus Clouds, Classification of, H. H. Hildebrandsson, 581
Civil: Engineering Geology, 732; Engineers, Institution of, awards of the, 645; Service Estimates, Education and Science in the, 557
Civilisation: and Primitive Peoples, H. Balfour, 753; énéolithique dans la Péninsule Ibérique, La, Dr. N. Åberg, 563
Clavaria, North American Species of, Prof. E. A. Burt, 28
Clay and Clay-mud, Physical Properties of, A. S. E. Ackermann, 200
Clays, The Constitution of, H. Ries, and others, 824
Climate, The Evolution of, C. E. P. Brooks, 561
Climates of the Past, Dr. W. R. Eckardt, 304
Climatic: Changes, Prof. J. W. Gregory, 561; Changes, their Nature and Causes, Prof. E. Huntington and S. S. Visher, 561; Continentality and Oceanity, L. C. W. Bonacina, 549
Climatological Normals for Egypt and the Sudan, 581
Clocks and Watches, G. L. Overton, 77
Cloud: Formation, Dr. C. Braak, 375; Forms according to the International Classification: The Definitions and Descriptions approved by the International Meteorological Committee in 1910, with an Atlas of Photographs of Clouds. 2nd edition, 107
Clouds, The Dissipation of, Prof. Bancroft and F. Warren, 265
Coal: and Allied Subjects, a Compendium of the First Ten Bulletins issued by the Lancashire and Cheshire Coal Research Association, F. S. Sinnatt, 631; a Series of Lectures on Coal and its Utilisation, H. Chamberlain, J. W. Cobb, R. Lessing, F. S. Sinnatt, and M. C. Stopes, 178; Gas, Charging for, on a Thermal Basis, Report on System for, 370; The Complete Gasification of, Dr. J. S. G. Thomas, 778; The Microscopic Structure of, W. N. Edwards, 690; The Utilisation of, Prof. H. Louis, 178; Mine Haulage, Methods and Costs of, Prof. H. Louis, 98; Mine Haulage in Illinois, A Study of, H. H. Stoek, J. R. Fleming, and A. J. Hoskin, 98; Mining, British, in the War Period, Prof. H. Louis, 766; Industry, the British, during the War, Sir R. A. S. Redmayne, 766
Cobalt Sulphate in Aqueous Solution, The Paramagnetism of, M. Chatillon, 903
Cocaine, and Possible Substitutes, appointment of a Committee on, 613
Cochlea: Mechanism of the, G. Wilkinson, 636; Prof. H. E. Roaf, 741
Cocoa Butter, Method of Analysis of, and its Mixtures with Vegetable Fats, M. Pichard, 727
Cod Liver Oil, The Experimental Conditions of the Action of, G. Mouriquand and P. Michel, 275
Coke, The Structure of, its Origin and Development, Sir George Beilby, 133
Cold Hardening by Drawing, P. Piketty, 275
Colias edusa, Curious Oviposition by a Specimen of the Clouded Yellow Butterfly, F. H. Lancum, 309
College Teaching, Methods of, Dr. W. W. Charters, 865
Colliers, Some Effects of High Air Temperatures and Muscular Exertion upon, K. N. Moss, 829
Colloid Chemistry: Laboratory Manual of, Prof. H. N. Holmes, 733; of the Proteins, Prof. W. Pauli. Translated by P. C. L. Thorne. Part I., 733
Colloidal: Behaviour, The Potential Difference occurring in a Donnan Equilibrium and the Theory of, Prof. A. V. Hill, 168; Suspensions, The Law of Distribution of Particles in, with Special Reference to Perrin's Investigations, pt. II., Prof. A. W. Porter and J. J. Hedges, 382
Colloids: and Staining, Sir W. M. Bayliss, 382; Some Moisture Relations of, Pt. I., E. A. Fisher, 169; II., 690; The Electric Charge of, Prof. H. R. Kruyt, 827; The Periodic Opacity of certain, in Progressively Increasing Concentrations of Electrolytes, J. Holker, 168
Colorado: Beetle, Leaflet on the, 543; River Basin, Geology of the, with reference to Engineering Problems, B. Willis, 26

Colour: and Methods of Colour Reproduction, Dr. L. C. Martin, with chapters on Colour Printing and Colour Photography, by W. Gamble, 799; Blindness, a New Method of Investigating, Dr. R. A. Houstoun and W. H. Manson, 795; Industry, The Synthetic, 212; Inheritance in Seeds and Flowers, I. Nagai, Dr. S. Ikeno, K. Miyake, and Y. Imai, 373; Photography, Practical, E. J. Wall, 531; Technology, The Physical Basis of, M. Luckiesh, 545; Temperature and Brightness of Moonlight, Dr. W. E. Forsythe, 533; Vision: a Discussion of the Leading Phenomena and their Physical Laws, Prof. W. Peddie, 799; and Colour Vision Theories, 799; in Lower Animals, A Direct Method of Testing, W. F. Hamilton, 207
Coloured Bows and Glories, The Formation of, B. B. Ray, 183
Colours, The Fading of, Sir Sidney Harmer, 130
Comet, Announcement of a New, W. N. Abbott, 857
Comets, Astrology of, 179
Compressibility, Internal Pressure, and Atomic Magnitudes, T. W. Richards, 763
Concilium Bibliographicum, The, Dr. J. Strohl, L. B. Prout, and G. Talbot, 880
Concrete: and Reinforced Concrete, W. N. Twelvetrees, 78; Reinforced, a Practical Handbook for use in Design and Construction, R. J. H. Hudson, 630
Condenser Corrosion, Bacteria and, R. Grant, E. Bate, and W. H. Myers, 236
Conjoint Board of Scientific Societies, Dissolved, 438; Sir Herbert Jackson and Prof. W. W. Watts, 706
Consciousness, Primary and Secondary, May Sinclair, 309
Contact-Metamorphism in the Comrie Area of the Perthshire Highlands, C. E. Tilley, 902
Continental: Drift, Hypotheses of, Dr. H. Jeffreys, 495; Flotation and Drift, Prof. J. Joly, 79; Dr. H. A. Baker, 80
Copernicus, Polish Celebrations of the 450th Anniversary of the Birth of, 515
Copper: Age in Spain and Portugal, The, M. C. Burkitt, 563; Oxidation of, and the Reduction of Copper Oxide by a New Method, W. G. Palmer, 690
Coral Reefs, Drowned, South of Japan, Prof. W. M. Davis, 555
Cork Formation, Prof. J. H. Priestley and Miss L. M. Woffenden, 302
Corona of 1908, The, and Solar Prominences, J. Evershed, 785

CORRESPONDENCE.

Acquired Characters, the Inheritance of, Breeding Experiments on, J. T. Cunningham, 702
Actinium, The Relation of, to Uranium, Dr. A. S. Russell, 703
Adsorption and Hæmoglobin, Sir W. M. Bayliss, 666; Prof. A. V. Hill, 843; J. Barcroft; N. K. Adam, 844; W. E. L. Brown, 881
Aegilops, Chromosome Numbers in, Prof. J. Percival, 810
Age and Area: Hypothesis, The, J. Adams, 114; Dr. J. C. Willis, 115; in Biology, W. C. F. Newton, 48; in Natural Selection, Dr. H. L. Clark, 150; J. T. Cunningham, 287
Alpha Particles in Gases, Some Interesting Tracks of, R. W. Ryan and Prof. W. D. Harkins, 114
Aluminium and other Metals, Single Crystals of, Prof. A. W. Porter, 362; Dr. C. J. Smithells, 601
Amber and the Dammar of Living Bees, M. Stuart, 83
Anticyclones, The Cause of, R. M. Deeley, 83, 256, 634; Catharine O. Stevens, 150; Major A. H. R. Goldie, 429, 634; W. H. Dines, 495
Armaments, Science and, Dr. L. C. Martin, 82, 429; Dr. J. Weir French, 186
Aster tripolium on Salt Marshes, H. W. Chapman, 256
Atmospherics, R. M. Deeley, 362
Atom? A Static or Dynamic, Dr. N. R. Campbell, 569
Atomic Number 72, On the Missing Element of, Dr. D. Coster and Prof. G. Hevesy, 79; Prof. G. Urbain and Prof. A. Dauvillier, 218
Audibility, Zones of, The High Temperature of the Upper Atmosphere as an Explanation of, F. J. W. Whipple, 187
Audition, The Mechanism of, F. W. Kranz, 291
Auroræ, Recent, W. B. Housman, 706
Babylonians, Ancient, A Biochemical Discovery of the, L. J. Harris, 326
"Baccy-juice," The so-called, in the Waters of the Thames Oyster-beds, Dr. J. H. Orton, 773
Bacillaria paradoxa, Distribution of the Organ-pipe Diatom, F. Chapman, 15
Balfour, Sir Isaac Bayley, Prof. T. D. A. Cockerell, 150
Ball Hardness and Scleroscope Hardness, H. O'Neill, 430
Balmer Series Lines of High Frequency, Photography of, Prof. R. Whiddington, 636
Bergen Museum, The New Marine Biological Research Station of the, Prof. A. Brinkmann, 358
Beryllium Acetate, Basic, Crystal Structure of, Sir W. H. Bragg, 532; Dr. N. V. Sidgwick, 809
Breeding Experiments on the Inheritance of Acquired Characters, J. T. Cunningham, 702
British Association, The Local Handbook of the, T. Sheppard, 16
Broadcasting: Pictures, A Method of, Dr. E. E. Fournier d'Albe, 811; Transmitter, Sir Oliver Lodge, 13
Calendar Reform, L. C. W. Bonacina, 289
Celtium: and Hafnium, On, Dr. D. Coster and Prof. G. Hevesy, 462; Lines, On Urbain's, H. M. Hansen and S. Werner, 461
Chloroplasts and Cells, Prof. R. R. Gates, 635
Cochlea, Mechanism of the, G. Wilkinson, 636; Prof. H. E. Roaf, 741
Coloured Bows and Glories, The Formation of, B. B. Ray, 183
Concilium Bibliographicum, The, Dr. J. Strohl, 880
Conjoint Board of Scientific Societies, The Dissolution of the, Sir Herbert Jackson and Prof. W. W. Watts, 706
Continental: Flotation and Drift, Prof. J. Joly, 79; Dr. H. A. Baker, 80; Drift, Hypotheses of, Dr. H. Jeffreys, 495
Crystal, Molecular and, Symmetry, T. V. Barker, 632; Dr. J. W. Evans; G. Shearer and W. T. Astbury, 740
Crystals, Unusual, G. H. Martyn, 186
Cutting Tools, Action of, H. S. Rowell, 84
Cyclones, Tropical, Vertical Change of Wind and, S. K. Banerji, 668; Sir Napier Shaw, 702
Diabetes, Use of Yeast Extracts in, L. B. Winter and W. Smith, 327
Drayson Paradox, The, A. H. Barley, 291; The Writer of the Note, 292
Echinoderm Larvæ and their Bearing on Classification, Prof. E. W. MacBride, 47, 323; Prof. J. F. Gemmill, 47; Dr. Th. Mortensen, 322; Dr. F. A. Bather, 397.
Echinus miliaris, The Breeding Period of, Dr. J. H. Orton, 878
Economics, Science and, W. W. Leisenring, 571, 846; St. George Lane Fox Pitt, 670; Prof. F. Soddy, 669
Eel, The Life-cycle of the, in Relation to Wegener's Hypothesis, Dr. T. W. Fulton, 359; Dr. A. M. Davies, 496
Egyptian Water-clocks, Prof. W. M. F. Petrie, 569
Einstein Paradox, An, Prof. R. W. Genese, 742, 880
Electron, Positive, Speculation concerning the, Dr. H. H. Poole, 15
Electronic into Electro-magnetic Energy, The Transformation of, Dr. J. A. Gray, 878
Electrons: The Capture of, by Swiftly Moving Alpha Particles, Prof. B. Davis, 706; The Release of, by X-rays, Prof. S. Russ, 534
Elements, The Naming of, Dr. N. R. Campbell, 292
Elvers in Egyptian Waters, The Ascent of, G. W. Paget, 290
e/m, The Value of, R. T. Birge, 287
Erythrocytes, The Hæmoglobin Distribution on Surfaces of, Prof. B. S. Neuhausen, 16
Eyes, Divided Composite, Dr. J. W. H. Harrison, 81; A. Mallock, 82
Fern, Longevity in a, Dr. F. J. Allen, 742
Ferromagnetic Substances, The Relation of the Critical Constants and the True Specific Heat of, Dr. J. R. Ashworth, 773
Fishes, Fourteen Generic Names of, Official List of, Prof. C. W. Stiles, 809
Geber, The Identity of, Prof. J. R. Partington, 219

German Book Prices, Prof. D. H. Peacock, 362
Germanium, The Isotopes of, Dr. F. W. Aston, 771
Golgi Bodies in Protozoa, Stages of, Miss S. D. King and Prof. J. B. Gatenby, 326
Green Flash at Sunset, The, J. Evershed, 13
Gregarine Parasite of Leptoplana, A New, Prof. B. L. Bhatia, 116
Growth, Some Experiments on Rate of, in a Polar Region (Spitsbergen) and in England, Dr. J. H. Orton, 146
Hæmoglobin: Adsorption and, Sir W. M. Bayliss, 666; Prof. A. V. Hill, 843; J. Barcroft; N. K. Adam, 844; W. E. L. Brown, 881; The Measurement of the Rates of Oxidation and Reduction of, Dr. H. Hartridge and F. J. W. Roughton, 325; -Content and Surface of Red Blood-Cells, Relation between, Dr. E. Gorter, 845
Hafnium: On the New Element, Dr. D. Coster and Prof. G. Hevesy, 182, 252; The Optical Spectrum of, H. M. Hansen and S. Werner, 322; and New Zealand Sand, Dr. A. Scott, 598; and Titanium, Sir T. E. Thorpe, 252; W. L. Fox, 429
Hardness and Penetration, Experiments on, A. S. E. Ackermann, 17; E. Mardles; H. O'Neill, 116
Haze on Derby Day—June 6, Dr. J. S. Owens, 848
Heape and Grylls Rapid Cinema, The, W. Heape, 881
Hearing, The Resonance Theory of, Sir James W. Barrett; G. Wilkinson, 396; Prof. H. E. Roaf, 498
Heat, The Mechanical Equivalent of, Prof. T. H. Laby, 877
Helium: Neutral, The Spectrum of, Dr. L. Silberstein, 46; Prof. W. M. Hicks, 146; The Crossed-orbit Model of, its Ionisation Potential, and Lyman Series, Dr. L. Silberstein, 567; Tracks of *a*-Particles in, Prof. D. M. Bose and S. K. Ghosh, 463
Herapath's Artificial Tourmalines, Dr. M. Nierenstein, 291
Hermit-crab, The, and the Anemone, A. T. Watson, 464
Hydra, Green and Colourless, Prof. S. J. Hickson, 601
Hydrogen, Active: by the Action of an Acid on a Metal, Prof. A. C. Grubb, 600; by Electrolysis, Prof. A. C. Grubb, 671
Immunising Diseases, Epidemiology of, Martini's Equations for the, Dr. A. J. Lotka, 633; Prof. G. N. Watson, 808
Indian Sketches, A Lost Collection of, Lt.-Col. H. H. Godwin-Austen, 845
Industry, Labour and Science in, Prof. F. Soddy, 497; F. S. M., 498
Insects and Arachnida, Tactile Vision of, J. P. O'Hea, 498; G. H. Locket, 570
Insulin: Dr. H. H. Dale, 253; Effect of, upon Blood Sugar Concentration, L. B. Winter and W. Smith, 810
Ionised Gas, The Opacity of an, J. Q. Stewart, 186
Isotopic Ions, Separation of, J. G. Pilley, 848
Kammerer's, Dr.: Alytes, Dr. W. Bateson, 738, 878; Experiments, Prof. E. W. MacBride, 841
Labour and Science in Industry, Prof. F. Soddy, 497; F. S. M., 498
Lepidoptera, Spermatogenesis of the, Prof. J. Brontë Gatenby, 568; H. G. Cannon, 670
Light: Dispersion and Scattering of, in Gases and Liquids, The Complex Anisotropic Molecule in Relation to the Theory of, Prof. L. V. King, 667; Elements, The, and the Whole Number Rule, Dr. F. W. Aston, 739; -Quanta, The Nature of, H. Bateman, 567; Sensitiveness, Vision and, J. P. O'Hea, 705
Limiting Equality, The Definition of, Prof. G. H. Bryan, 183
Liquid State, The Nature of the, Prof. C. V. Raman; Sir W. H. Bragg, 428
Liquids, Viscosity of, A Theory of the, Prof. C. V. Raman, 532, 600; R. M. Deeley, 774
Lubrication, The Latent Period in, Ida Doubleday and W. B. Hardy, 182
Magnet, A Levitated, F. H. Glew, 669
Magnetic Disturbance of March 24-25, The, Rev. A. L. Cortie, 534
Maketu Sand, Black, Constitution of, Dr. C. J. Smithells and F. S. Goucher, 397; Dr. A. Scott, 463
Man, Biology of, Prof. Karl Pearson; J. S. H., 809
Martini's Equations for the Epidemiology of Immunising Diseases, Dr. A. J. Lotka, 633; Prof. G. N. Watson, 808
Medical Education, Sir G. Archdall Reid, 50, 324; Prof. W. J. Dakin, 151
Megalithic Monuments, Distribution of, O. G. S. Crawford, 602
Mendelian Genes, The Function of, J. S. Huxley, 286; Prof. E. W. MacBride, 394
Mentone, The Phantom Island of, Prof. G. H. Bryan, 430
Mercury: A New Phototropic Compound of, Prof. Y. Venkataramaiah and Bh. S. V. Raghava Rao, 775; Separation of, into Isotopes in a Steel Apparatus, Prof. W. D. Harkins and S. L. Madorsky, 148
Metallic Crystals and Polarised Light, J. H. Shaxby, 431
Metals, Pressure of Fluidity of, A. S. E. Ackermann, 534
Meteorite at Quetta, Slag mistaken for a, G. H. Tipper, 704
Meteorological: Disturbance, A, of an Oscillatory Character, Prof. W. G. Duffield, 598; Nomenclature and Physical Measurements, Sir Napier Shaw, 218; Dr. H. R. Mill, 327
Microphonic Flames, Dr. Lee de Forest, 739
Microscope, Industrial Applications of the, A. G. Lowndes, 358
Microscopic Bodies, The Determination of *p*H of, C. F. A. Pantin, 81
Millibar in Aerodynamics, Use of the, Major A. R. Low, 535
Mirage, A Double-Vertical-Reflection, at Cape Wrath, D. Brunt, 222
Molecular: and Crystal Symmetry, T. V. Barker, 632; Dr. J. W. Evans; G. Shearer and W. T. Astbury, 740; Oscillation, Selective Interruption of, A. Fairbourne, 149; R. d'E. Atkinson, 326
Moonlight, Colour Temperature and Brightness of, W. E. Forsythe, 533
Museums, Prof. T. D. A. Cockerell, 184
Nature Study and Phenology, J. E. Clark and I. D. Margary, 49
Nebulæ, Spiral, Gravitation and Light-Pressure in, Sir Oliver J. Lodge, 702; Dr. J. H. Jeans, 806; Prof. F. A. Lindemann, 806, 881
Nightingale in Uganda, Dr. G. D. Hale Carpenter, 636
Nitrogen: and Hydrogen, The Ionising Potentials of, Dr. H. D. Smyth, 810; Fixation of, by Plants, E. Whitley, 187
Nomenclature, The Rule of Priority in, F. Chapman, 148; Dr. F. A. Bather, 182
Occult Phenomena and After-images, Dr. F. W. Edridge-Green, 16
Odorous Strength, Factors of, T. H. Durrans; F. H. Perrycoste, 359
Organ-pipe Diatom (*Bacillaria paradoxa*), Distribution of the, J. W. Williams, 116
Overvoltage, The Measurement of, Dr. S. Glasstone, 775
Oxygen and Hæmoglobin, The Combination between, and the Criteria of Adsorption, N. K. Adam, 496
Oysters and other Lamellibranchs, The Cause of Chambering in, Edith Worsnop and Dr. J. H. Orton, 14
Palæontology and Archaic Fishes, Prof. J. Graham Kerr, 113
Paradromic Rings, Dr. G. T. Bennett, 882
Permanent Image on Clear Glass, A, E. Robinson, 569; Dr. J. W. French, 570; Dr. T. J. Baker, 743
Perseid Meteors in July 1592, Dr. J. K. Fotheringham, 774; W. F. Denning, 848
Phosphates as Fertilisers, Discovery of the Use of, Sir John Russell and A. Henderson Smith, 116
Phosphorescence caused by Active Nitrogen, Prof. E. P. Lewis, 599; W. Jevons, 705
Physical Literature on the Continent, Dr. R. W. Lawson, 635
Planck Constant *h*, The Value of the, R. T. Birge, 811
Pond Snail, The Name of the, F. A. B., 150
Porto Santo in Pleistocene Times, Prof. T. D. A. Cockerell, 464
"Principia," Definitions and Laws of Motion in the, Prof. W. Peddie; F. E. Hackett, 395
Psilotaceæ, Modern, and Archaic Terrestrial Plants, Prof. B. Sahni, 84
Puzzle Paper Band, A, Prof. C. V. Boys, 774; Annie D. Betts; Dr. G. T. Bennett, 882
Radioactive Disintegration, Origin of, S. Rosseland, 357
Rainfall Data, Paradoxical, Prof. A. M'Adie, 362; R. A. Fisher, 465
Rana temporaria, An Overlooked Feature in Four-legged Tadpoles of, O. H. Latter, 151

Rat Repression, The Rodier System of, A. E. Moore, 671
Relativity-predicted Mechanical Effect in the Electromagnetic Field, A, Prof. A. M'Aulay, 325
Resonance: Multiple, P. Rothwell, 254; Radiation, Destruction of the Polarisation of, by Weak Magnetic Fields, Prof. R. W. Wood and A. Ellet, 255
Rodier System of Rat Repression, The, A. E. Moore, 671
Russian Proper Names, Transcription of, Prof. B. Brauner, 290
Sand, Crushed, Law governing the Connexion between the Number of Particles and their Diameters in Grinding, C. E. Blyth, Dr. G. Martin, and H. Tongue, 842
Sarsen Stones, C. Carus-Wilson, 292
Science: and Armaments, Dr. L. C. Martin, 82, 429; Dr. J. Weir French, 186; and Economics, W. W. Leisenring, 571, 846; St. George Lane Fox Pitt, 670; Prof. F. Soddy, 669; The Social Influence of, Ad. K., 361; F. S. Marvin, 362
Scientific Periodicals for Czech Students, B. O. Tufnell, 397
Seeds, the Germination of, Effect of Moonlight on, Elizabeth Sidney Semmens, 49
Segregation, Selection and, Prof. A. Willey, 602; Sir G. Archdall Reid, 806
Selection and Segregation, Prof. A. Willey, 602; Sir G. Archdall Reid, 806
Silent Zone in Explosion Sound-areas, The, Dr. C. Davison, 117
Silica, Vitreous, The Hardness of, C. Johns and Prof. C. H. Desch, 15
Smell and Specific Gravity, J. H. Kenneth, 151
Soaring Flight and the "Olfactory" Organs of Birds, Lt.-Col. W. E. M'Kechnie, 48
Soil Reaction, Water Snails and Liver Flukes, Dr. W. R. G. Atkins and M. V. Lebour, 83; C. L. Walton, 117
Specific Gravity, Smell and, J. H. Kenneth, 151
Spiranthes Autumnalis, Prof. F. O. Bower, 185; E. P. Smith; J. B. Simpson, 291
Stark Effect, Easy Method of observing the, Prof. H. Nagaoka and Y. Sugiura, 431
Stirling's Theorem, Prof. J. Satterly, 220; J. Strachan, 397; H. E. Soper, 601
Stoat's Winter Pelage, The, Sir Herbert Maxwell, 220; J. Parkin; Dr. J. Ritchie; R. de J. F. Struthers, 360
Stonehenge: Concerning the Four Stations, E. H. Stone, 220
Subject Index to Periodicals, The, E. W. Hulme, 360
"Sucking-fish," The Adhesive Apparatus of the, Sunder Lal Hora, 668
Sugar: Blood, Effect of Plant Extracts on, Prof. J. B. Collip, 571; Cane Mealy-bug, The, Prof. T. D. A. Cockerell, 223
Symmetry, Molecular and Crystal, T. V. Barker, 632; Dr. J. W. Evans; G. Shearer and W. T. Astbury, 740
Tertiary Brachiopods from Japan, J. W. Jackson, 809
Tesla Spectra: and the Fraunhofer Effect in Complex Compounds, J. K. Marsh and Prof. A. W. Stewart, 115; of Complex Compounds, Prof. V. Henri; J. K. Marsh and Prof. A. W. Stewart, 289
Thermal Opalescence in Crystals and the Colour of Ice in Glaciers, Prof. C. V. Raman, 13
Time Relations in a Dream, Dr. W. R. G. Atkins, 117; H. F. Biggs, 290; M. Gheury de Bray, 361
Triode Valve in Spectrometry, Use of the, L. Bellingham, 534
Tropical Agriculture, Educational Problems of, Prof. W. R. Dunlop, 880
Ultramicrometer, The Recording, J. J. Dowling, 742
Upper Atmosphere, The High Temperature of the, Prof. F. A. Lindemann and G. M. B. Dobson, 256
Uranium, The Relation of Actinium to, Dr. A. S. Russell, 703
Vertical Beam, "Artificial," W. C. Baker, 185
Vision: and Light Sensitiveness, J. P. O'Hea, 705; Tactile, of Insects and Arachnida, G. H. Locket, 848
Volcanic: Activity in Iceland and Long Distance Transport of "Dust," J. N. Carruthers, 255; Dust and Climatic Change, Prof. W. J. Humphreys, 431
Water Snails and Liver Flukes, A. W. Stelfox; Dr. Monica Taylor, 49
Waterspouts, D. Brunt; H. E. Hornby, 82
Wave Theory, The, and the Quantum Theory, Prof. C. G. Darwin, 771
Wegener Hypothesis: The, and the Origin of the Oceans, T. Crook, 255; The Life-cycle of the Eel in relation to, Dr. T. W. Fulton, 359; Dr. A. M. Davies, 496; of Continental Drift, The, Dr. J. W. Evans, 393; and the Great Pyramid, Dr. G. P. Bidder, 428; Prof. W. M. F. Petrie, 429; Botanical Aspects of, Prof. R. H. Compton; The Writer of the Article, 533; The Zwartebergen and the, W. B. Wright, 569
Wren's, Sir Christopher, Science Museum, R. T. Gunther, 288
X-rays in Liquids, The Scattering of, Prof. C. V. Raman, 185
Zoological Nomenclature: Musca and Calliphora, Prof. C. W. Stiles, 115

Corris and Aberllefenni (Merioneth), Geology of the District around, W. J. Pugh, 794
Corrosion, Alloys resistant to, Sir Robert Robertson and others, 619
Corundum Rocks, The Prochlorites of, J. Orcel, 728
Cosmogony, Modern, Dr. H. Jeffreys, 662
Cottage-building, A Graphical Cost Analysis of, W. H. Wainwright, 415
Cotton, The Cuticle of, R. G. Fargher and M. E. Probert, 443
Cracow University, conferment of a degree on the Earl of Balfour, 688
Creosote, Beechwood, Heavy Oils of, Specific Characters of the, Bordas and Touplain, 763
Cresson, Elliott, gold medal of the Franklin Institute, the, presented to Dr. L. de Forest, 337
Crime and Poisoning, Lt.-Col. J. A. Black, 268
Criminal Responsibility, Psychology and, Dr. W. Brown, 581
Crinoids, The Rôle of the, in the History of the Secondary Oolitic Iron Minerals, L. Cayeux, 903
Croix de chevalier du Mérite Agricole, awards of the, 92
Crown Gall on Nursery Stock, H. Wormald, 274
Cruciferæ, A Taxonomic Study in the, E. B. Payson, 683
Crustacean Limb, Primitive, Character of the, E. W. Shann, 59
Cryptography, A. Langie, translated by J. C. H. Macbeth, 737
Crystal: Analysis, New Methods of, and their Bearing on Pure and Applied Science, Sir William Bragg (Trueman Wood Lecture), Supplement (June 9) iii, 781; Growth in Cadmium, M. Cook, 382; Molecular and, Symmetry, Dr. J. W. Evans; G. Shearer and W. T. Astbury, 741; Receivers for Broadcast Reception, P. W. Harris, 628; Structure of Basic Beryllium Acetate, Sir William Bragg, 532; The Reflection by a, of X-rays characteristic of Chemical Elements in it, G. L. Clark and W. Duane, 868
Crystalline Liquids, Sir William Pope, 99
Crystals: Atomic Radii in, Dr. R. W. G. Wyckoff, 720; Photo-electric Conductivity of, Drs. B. Gudden and B. Pohl, 859; Single, of Aluminium and other Metals, Dr. C. J. Smithells, 601; The Abnormal Reflection of X-rays by, G. L. Clark and W. Duane, 868; Unusual, G. H. Martyn, 186
Ctenophores, Aberrant, Development of some, Prof. T. Komai, 95
Cubit, An Old-World, in America, Prof. W. M. Flinders Petrie, 647
Cucumber Woodlouse, Action of Simple Aromatic Compounds on the, E. R. Speyer and O. Owen, 553
Cullum gold medal of the American Geographical Society awarded to E. A. Reeves, 92
Culture Media, Organisms in, Distribution of, R. A. Fisher, H. G. Thornton, and W. A. Mackenzie, 443
Cumene and *p*-Cymene, A New Synthesis of, L. Bert, 520
Currant, Black, Early History of the, 411
Curve Fitting, S. Krichewsky, 824
Cutting Tools, Action of, H. S. Rowell, 84
Cuttings, The Rooting of, Prof. J. Small, 823
C Vitamins, Utilisation by the Organism of the, introduced through the Parents, E. Lesné and M. Vaglianos, 451
Cyclic Growth, The Statistics of, H. S. Reed, 763

Cyclones: and Anticyclones, The Mechanism of, T. Kobayasi, 587; Extratropical, The Mechanism of, S. Fujiwhara, 310; The Origin of, Dr. S. K. Banerji, 413; Tropical, Vertical Change of Wind and, Dr. S. K. Banerji, 668
Cylinder, The Resistance of a, moving in a Viscous Fluid, Prof. L. Bairstow, Miss B. M. Cave, and Miss E. D. Lang, 241
Cylindrospermum from Bengal, A New Species of, P. Brühl and K. Biswas, 555
Cypræideæ, Gasteropods of the Family of the, The Characters suitable for Classifying the, A. Vayssière, 831
Cytospora, British, W. B. Grove, 480

Dana Expedition, Some Deep-sea Fishes taken by the, C. Tate Regan, 867
Daphnia pulex L., Changes in the Specific Gravity of, Miss D. Eyden, 243
Dartmoor: Granite, The (Widecombe area), A. Brammall and H. F. Harwood, 486; Occurrences of Rutile, Brookite, Anatase and Zircon, A. Brammall and H. F. Harwood, 135
Darwinian theory, attacks upon the, 818
Date Palms of Iraq, V. H. W. Dowson, 719
Daturas, The Reduction Division in Haploid, Diploid, Triploid and Tetraploid, J. Belling and A. F. Blakeslee, 867
Davison, Henry P., scholarships, the, 621, 651
Davyne-like Mineral, A, and its Pseudomorphs from St. John's Island, Egypt, Dr. L. J. Spencer, E. D. Mountain, and W. C. Smith, 135
Day-Dreams, The Psychology of, Dr. J. Varendonck, 12
Dayton University, Ohio, Dr. P. Knoller appointed professor of mineralogy and petrography at, 890

DEATHS.

Abraham (Prof. M.), 506
Acton (Dr. Elizabeth), 781
Aldous (Rev. J. C. P.), 298
Barnard (Prof. E. E.), 298, 367
Boruttau (Prof. H.), 888
Bosanquet (B.), 230
Bryant (W. W.), 229
Bullen (G. E.), 506
Burne (Miss Charlotte Sophia), 156
Butler (Prof. A. S.), 335, 474
Caldwell (Prof. J. W.), 298
Carnarvon (Lord), 504
Chiene (Prof. J.), 781
Clarke (Sir Ernest), 335
Cohn (Prof. F.), 194
Cox (Prof. J.), 678, 817
Curtis (A. H.), 125
Dalton (Dr. N.), 368
Davids (Prof. Rhys), 58
Dewar (Sir James), 472
Dogiel (Prof. A. S.), 437
Duncan (Dr. D.), 749
Elliott (Prof. J. A.), 298

Weston (F. E.), 230
Wilks (Rev. W.), 335, 403
Woll (Prof. F. W.), 229
Wragge (C. L.), 23
Wright (J.), 578, 677

Decapod Crustacea, S. W. Kemp, 656
Dehydrating Alcohol and certain Organic Liquids, A Continuous Method of, H. Guinot, 903
Density Determinations, Some, A. C. Egerton and W. B. Lee, 381
Depth Chart, A Simple Form of Photographic, Rev. H. C. Browne, 831

Design in Modern Industry: The Year-Book of the Design and Industries Association, 1922, 181
Determinants, Elementary, for Electrical Engineers, H. P. Few, 566
Déterminisme et l'adaptation morphologiques en biologie animale, Prof. R. Anthony. Première partie, 664
Development Commissioners, Report of the, 127
Devonian Formation in Australia, The, Dr. W. N. Benson, 719
Dextro Malic Acid and the Utilisation of Ammonium Molybdomalate for the Resolution of Racemic Malic Acid, E. Darmois and J. Périn, 310
Dhammapada, The 44th Verse of the, J. van Manen, 832
Diabetes, Use of Yeast Extracts in, L. B. Winter and W. Smith, 327
Diacetyl, The Ultra-Violet Absorption Spectrum of, C. Lardy, 867
Differential Equations, A certain Family of Periodic Solutions of, with an Application to the Triode Oscillator, W. M. H. Greaves, 725
Diffraction Spectra produced by Round Corpuscles Irregularly Distributed, A. Druault, 103
Diffusion in Solid Solutions, H. Weiss and P. Henry, 103
Diphtheria, Domestic Animals in Relation to, 576
Dipnoi, The Occipital Bones of the, H. S. Baird, 311
Disease: Sunlight and, Dr. C. W. Saleeby, 574; The Antiquity of, Prof. R. L. Moodie; Prof. G. Elliot Smith, 874
Dog's distemper, appointment of a committee upon, 337; an inquiry into, 366
Dolmen, a, discovered at St. Ouens, Jersey, 336
Dolomite, The Dissociation of, C. S. Garnett, 486
Domestic Animals in Relation to Diphtheria, 576
Dominion Museum Monographs, Nos. 1 to 4, E. Best, 790
Drayson Paradox, The, A. H. Barley, 94, 291; The Writer of the Note, 292
Drought of 1922–23 on Table Mountain, The, T. Stewart, 796
Duddell Memorial of the Physical Society, The, 686
Durham University, impending retirement of Prof. H. Louis; Prof. G. Poole appointed professor of mining; Dr. J. A. Smythe appointed the William Cochrane lecturer in metallurgy, 484; Prof. G. H. Thomson to lecture at the Teachers' College, Columbia University, 485
Dusuns of British North Borneo, The, G. Hewett, 450
Dutch East Indian Seas, Scientific Work in the, Dr. W. G. N. van der Sleen, 9
Dyers, Worshipful Company of, the Research Medal of the, awarded to Prof. G. T. Morgan, 25
Dyes, The Manufacture of, Dr. J. C. Cain, 212
Dyestuffs Industry, The, in Relation to Research and Higher Education, Dr. H. Levinstein, 445
Dynamometer Springs, Influence of the Velocity of Impact in the Calibration of, C. Frémont, 171

Early World, Stories from the, R. M. Fleming, 284
Earth: The, under the Rule of Man, Prof. G. A. J. Cole, 352; Blocks, Crumpling and Rifting of, O. Baschin, 548
Earthquake: a great submarine, 231; a violent, on February 4, 196; Foci, Depth of, Dr. Dorothy Wrinch and Dr. H. Jeffreys, and others, 585; of October 12, 1922, The, in the Creuse and the Limousin, and some Earthquakes in the North-west of the Central Massif, P. Glangeaud, 452; Periodicity and Tidal Stresses, L. A. Cotton, 412
Earthquakes: of the East Indian Archipelago, Dr. S. W. Visser, 199; Periodicity of, D. Mukiyama and M. Mukai, 444; The Character and Cause of, R. D. Oldham, 432
Earth's: Crust, Movements of the, Prof. H. Stille, 759; the Elements in the, The Relative Abundance of, A. J. Lotka, 764; The Surface Movements of the, Prof. J. Joly, 603; Electric and Magnetic Fields, The, Prof. W. F. G. Swann, 640, 673; Interior, Condition of the, Prof. T. C. Chamberlin, 129
Earthworm, The Nerve Net in the, W. M. Smallwood, 764
Eastern Kara-koram and Khotan, Surveys in the, Major H. Wood, 340
Echinoderm Larvæ and their Bearing on Classification, Prof. E. W. MacBride; Prof. J. F. Gemmill, 47; Dr. Th. Mortensen, 322; Prof. E. W. MacBride, 323; Dr. F. A. Bather, 397
Echinus miliaris, The Breeding Period of, Dr. J. H. Orton, 878
Eclipse: the Recent, Einstein and, 541; of September 1922, Observations at Wallal of the, J. Hargreaves and G. S. Clark-Maxwell, 128; in Queensland, The, J. C. Russell, 441
Economic Biologists, Association of, Election of Officers and Council of the, 196
Economics, Science and, W. W. Leisenring, 571, 846; Prof. F. Soddy, 669; St. George Lane Fox Pitt, 670
Edinburgh University: impending retirement of G. G. Chisholm, 133; gift by J. A. Hood; Dr. M. Wilson appointed reader in mycology and bacteriology; Dr. H. Robinson reader in experimental physics; Dr. G. A. Carse reader in natural philosophy; the Cameron prize awarded to Prof. J. J. R. Macleod, 273; speech of Mr. Lloyd George to the Union, 380; Technical Chemistry at, 826
Education: Adult, in Rural Areas, 345; and Science in the Civil Service Estimates, 557; Geography in, 64; Higher: in Australia and New Zealand, Dr. C. F. Thwing, 308; Research in the Scheme of, Dr. H. H. Hodgson, 343; in the Empire, Progress of, since 1911, H. A. L. Fisher, 865; preparatory general, excessive prolongation of, criticised, 901; Synthetic, An Experiment in, Emily C. Wilson, 217; Technical, The Position of, W. R. Bower, 760; University and Secondary, 833
Educational Publications, Record of, 205
Eel: Breeding Places and Migrations of the, Dr. Johs. Schmidt, 51; The Life Cycle of the, in Relation to Wegener's Hypothesis, Dr. T. W. Fulton, 359
Egypt: Ancient, The Sed Festival of, P. E. Newberry, 378; The Sun-Cult in, Dr. A. M. Blackman, 499, 536; Weaving in, 129; Ministry of Public Works, Report of the Physical Department, 614; Palæopathology of, Studies in the, Sir Marc Armand Ruffer. Edited by Prof. R. L. Moodie, 874
Egyptian: Chronology, Ancient, Dr. H. R. Hall, 776; Water-clocks, Old, 479; Prof. W. M. F. Petrie, 569; World, The, in the Time of Tutankhamen, Dr. H. R. Hall, 398
Eidamia: from Apple grown in Sugar Solutions, A. S. Horne and H. M. Judd, 553; from Oak and the Production of a Yellow Colour in Seasoned Wood, H. S. Williamson, 553; Two New Species of, A. S. Horne and H. S. Williamson, 553
Einstein: and the Recent Eclipse, 541; Paradox, An, Prof. R. W. Genese, 742, 880; L'Évidence de la théorie d', Prof. P. Drumaux, 697
Electric: Charge of Colloids, The, Prof. H. R. Kruyt, 827; Clock, An, with Detached Pendulum and Continuous Motion, A. Steuart, 420; Conduction, Hall's Theory and Perkins' Phenomenon, E. B. Wilson, 868; Conductors, Heating in, S. W. Melsom and E. Fawssett, 375; Shock, Treatment of, Sir Bernard Spilsbury and others, 718; Transients, Prof. C. E. Magnusson, A. Kalin, and J. R. Tolmie, 840
Electrical: Distribution on two Spherical Conductors, Dr. U. Russell, 62; Engineering, 458; Alternating Current, R. Kemp. Second edition, 427; Engineers: Institution of, presentation of the Faraday medal to the Hon. Sir Charles Parsons, 750; Standard Handbook for, Editor-in-Chief, F. F. Fowle. Fifth edition, 458; Science, History of, 142; Theory, Modern, Supplementary Chapters. Chapter xvi.: Relativity, Dr. N. R. Campbell, 697
Electricity and Magnetism, Bibliographical History of, chronologically arranged, Dr. P. F. Mottelay, 142
Electro-Cardiogram, Influence of Mechanical Conditions of the Circulation on the, I. de B. Daly, 653
Electrolysis with an Aluminium Anode, F. H. Jeffery, 382
Electrolytic Conduction: Sequel to an Attempt (1886) to apply a Theory of Residual Affinity, Prof. H. E. Armstrong, 689

Electromagnetic: Field, A Relativity-predicted Effect in the, Prof. A. McAulay, 325; Inductor, An, L. F. Richardson, 691; Waves, The Propagation of, maintained along two Parallel Wires, G. Laville, 451
Electrometer, Filament, A New, Dr. C. W. Lutz, 788
Electro-motive Forces, The Production of, by Heating Junctions of Single Metals, C. R. Darling and C. W. Stopford, 623
Electron: A Decade in the History of the, Sir Ernest Rutherford, 99; Positive, Speculation concerning the, Dr. H. H. Poole, 15; The, in Chemistry, Sir J. J. Thomson, 100
Electronic into Electro-magnetic Energy, The Transformation of, Dr. J. A. Gray, 878
Electrons: The Capture and Loss of, by α-Particles, Sir Ernest Rutherford, 519; The Capture of, by Swiftly Moving Alpha Particles, Prof. B. Davis, 706; The Release of, by X-rays, Prof. S. Russ, 534
Electro-phonographic Method, The, and its Use for the Registration of Sounds, A. Blondel, 103
Element 72 (Celtium), The K Absorption Spectrum of, M. de Broglie and J. Cabrera, 347
Elements, The Naming of, Dr. N. R. Campbell, 292
Elephants (Recent and Fossil) in the British Museum (Natural History), second edition of the Guide to the, 26
Elephas planifrons, Presence of, in the Red Crag (English Upper Pliocene), G. Pontier, 275
Ellipsoidal Particles, The Motion of, in a Viscous Fluid, G. I. Taylor, 241
Elvers in Egyptian Waters, The Ascent of, G. W. Paget, 290
e/m, The Value of, R. T. Birge, 287
Emotion, The Measurement of, W. W. Smith, 316
Empire: Forestry Association, acceptance of the presidency of the, by the Prince of Wales, 299; The Northward Course of, V. Stefansson, 839
Empire's Telegraphs and Trade, The Relation between the, Sir Charles Bright, 371
Engineering: Geology, Elements of, Profs. H. Ries and T. L. Watson, 732; Joint Council, The Constitution and By-Laws of the, 715; Psychology in, Sir William Ashley, 302
Engineers, The Scientific Education of, Sir Richard Glazebrook, 724
England and Wales, The Races of, a Survey of Recent Research, Prof. H. J. Fleure, 737
Enteropneust, A New British, Prof. A. Meek, 340
Entertainment Tax, The, and Museums, 230
Enzymes, two Typical, The Chemical Nature of, H. C. Sherman, 763
Eötvös: Gravity Balance, The, Capt. H. Shaw and E. Lancaster-Jones, 617, 691, 849
Epizootic Abortion, etc., The Micro-organism of, C. Nicolle, E. Burnet, and E. Conseil, 655
Eriostemon Crowei (*Crowea saligna*), The Essential Oil of, A. R. Penfold and F. A. Morrison, 311
Erythrocytes, The Hæmoglobin Distribution on Surfaces of, Prof. B. S. Neuhausen, 16
Etesiens in the Mediterranean, The, J. S. Paraskévopoulos, 199
Ethyl Alcohol, The Denaturation of, F. Bordas and T. Touplain, 554
Etna, eruption of, 889
Eucalyptus cneorifolia, The Economic Utilisation of the Residues from the Steam Rectification of the Essential Oil of, A. R. Penfold and R. Grant, 311
Europäischen Bienen, Die (Apidæ). Das Leben und Wirken unserer Blumenwespen, Prof. H. Friese. 1 Lief., 250
"Event"? What does Dr. Whitehead mean by, Sir Leslie Mackenzie, 902
Everest, Mount, Expedition, pictures of the, 127
Everyday Life in the New Stone, Bronze, and Early Iron Ages, Marjorie and C. H. B. Quennell, 700
Evolution: as applied to Man, the Teaching of, The American Association and, 299; of Man, The, a Series of Lectures delivered before the Yale Chapter of the Sigma Xi during the Academic Year 1921–1922, by Prof. R. S. Lull and others. Edited by G. A. Baitsell, 735; Religion and, Rev. Canon E. W. Barnes, 526; The Trend of, 735
Exhibition: of 1851, Commissioners for the, award of Senior Studentships, 901; of Physical Apparatus, 63
Explosion: -waves in Sea-water, Determination of Velocity of; Variation of Velocity with Temperature, A. B. Wood, H. E. Browne, and C. Cochrane, 381; Motors, Friction Losses in, Influence of Velocity and of Temperature on the, A. Planiol, 655
Explosive Wave, Formation of the, P. Lafitte, 795
Explosives: Firing, appointment of a sub-committee on the means employed for, 477; High, Calorimetry of, Sir R. Robertson and W. E. Garner, 689
Expressionism in Art: its Psychological and Biological Basis, Dr. O. Pfister. Translated by Barbara Low and Dr. M. A. Mugge, 736
Eye, Hereditary Diseases of the, 492
Eyes, Divided Composite, Dr. J. W. H. Harrison, 81; A. Mallock, 82
Eyesight, alleged dangers to, by electric light, 298

Falkland Islands, scientific researches in the, appointment of a committee to control, 542
Far Eastern Association of Tropical Medicine, Dr. A. E. Horn elected president of the Malaya meeting, 26
Farbenchemie, Grundlegende Operationen der, Prof. H. E. Fierz-David. Zweite Auflage, 142
Farm: Animals, Cyclopedia of. Edited by L. H. Bailey, 140; Buildings, W. A. Foster and D. G. Carter, 391; Costing and Accounts, C. S. Orwin, 804; Crops, Cyclopedia of, a Popular Survey of Crops and Crop-making Methods in the United States and Canada. Edited by L. H. Bailey, 140
Farming Industry, the present position of the, Interim Report upon, 542
Faroe Islands, Linguistics and Phonetics of the, J. D. Price, 198
Fatigue in Laundry Work, Miss May Smith, 410
Fauna of an Indian Island, The, 378
Faune de France, 4: Sipunculiens, Échiuriens, Priapuliens, Prof. L. Cuénot, 356
Fern, Longevity in a, Dr. F. J. Allen, 742
Ferns, Epiphytic, Exhibit of, at the Royal Botanic Gardens, Kew, 93
Ferric-hydroxide in Water, Evolution of the Molecule of, Mlle. S. Veil, 171
Ferromagnetic Substances, The Relation of the Critical Constants and the True Specific Heat of, Dr. J. R. Ashworth, 773
Fibres from the Tropics, E. Mathieu and others, 411
Ficaria, The Number of Cotyledons of, P. Bugnon, 488
Field Museum of Natural History, Annual Report of the, for 1921, 544
Filaments, Rotation of the, New Measurements of the Velocity of, L. d'Azambuja, 588
Filature, Manuel de, F. Rubigny, 356
Films, Thin, The Structure of, N. K. Adam, Pts. IV. and V., 793
Firearms and Projectiles, The Examination of, A. Lucas, 419
Fireball: Great, in Northern India on December 28, 1922, W. F. Denning, 372; in January, W. F. Denning, 197
Fire-making in the Malay Peninsula, I. H. N. Evans, 683
Fishery: Board for Scotland, Dr. A. Bowman appointed superintendent of scientific investigations, 782; research in Lancashire, 517
Fishes, Fourteen Generic Names of, Official List of, Prof. C. W. Stiles, 809
Flight Compass, New, P. R. Heyl and L. J. Briggs, 29
Flora of New Zealand, 457
Flower Petals, Size Characters in, The Non-Mendelian Inheritance of, Prof. R. R. Gates, 893
Flying records, new, 543
Food-stuffs, Manufacture of Papers for Wrapping and Containing, J. Strachan, 553
Foods and Drugs, The Microscopical Examination of, Prof. H. G. Greenish. Third edition, 459
Foraminiferal Sands in Corsica, E. Heron-Allen and A. Earland, 412
Forecast Code for the Abbreviation of Weather Forecasts transmitted by Telegraphy or Radiography, 107

Forecasting Weather, An Introduction to, P. R. Zealley, 12
Forest, The Murmur of the, and the Roar of the Mountain, Prof. W. J. Humphreys, 481
Formaldehyde, The Influence of, on the Higher Plants, E. and G. Nicolas, 103
Formalism and Mysticism, Prof. H. Wildon Carr, 246
Formosa, Among the Head-hunters of, Janet B. Montgomery McGovern, 284
Forrest, James, lecture, Sir Richard Glazebrook, 709
Fossil: Coniferous Genus Pitys, W. T. Gordon, 726; Mammals from Bolivia, 699
Fossilised Human Skull in Santa Cruz, Discovery of a, Dr. Wolf, 336
Fossils as Age-markers in Geology, The, G. McC. Price, 854
Foulerton: professor, Prof. E. H. Starling appointed, 196; research studentship, Dr. H. W. C. Vines appointed to a, 196
Fountain of Youth, The (Silver Spring), E. Imbeaux, 103
Fourier-Bessel Function, The, Sir G. Greenhill, 422
Franken und Westgoten in der Völkerwanderungszeit, Die, Dr. N. Åberg, 454
Franklin Institute: presentation of the Howard N. Potts gold medal to Dr. A. W. Hull and the Edward Longstreth medal to the Société Genevoise d'Instruments de Physique of Geneva, 751; work and awards of the, 440
Free: -Air Pressure Maps for the United States, C. Le Roy Meisinger, 788; Will, The Problem of, in the Light of Recent Developments in Philosophy, C. E. M. Joad, 346
French Pyrenees, The Glaciations of the Valleys of the, and their Relations with the Fluvial Terraces, C. Depéret, 867
Frog, Decerebrate and Spinal, Reflex Contractions of the Cruralis Muscle in the, N. B. Laughton, 274
Fruit Trees, Investigations upon, L. N. Staniland and others, 823
Fuel: -Oil, Burning Heavy, H. Moore, 29; Research Board: local committees on the survey and classification of coal-seams, 891; resignation by Sir George Beilby of the directorship of fuel research and chairmanship of the Board; Dr. C. H. Lander appointed director of fuel research and Sir Richard Threlfall chairman, 855
Fuels: American, Dr. R. F. Bacon and W. A. Hamor. 2 vols., 835; Technology of, Prof. J. W. Cobb, 835
Fungus, Bacterial, and Allied Diseases on Crops in England and Wales, 1920–21, 416
Fusarium: Experiments on Growth-rate and Cultural Factors of the same Species of, W. Brown, 274; The Systematic Characters of Closely Allied Strains of, A. S. Horne, 274

Galvanometer, A New Moving-coil, of Rapid Indication, W. J. H. Moll, 622
Gamma Rays of the Radium and Thorium Family studied by their Photo-electric Effect, de Broglie and J. Cabrera, 275
Ganges, Fauna of the, The Marine Element in the, Dr. N. Annandale, 893
Gas: A Non-Uniform Rarefied, Free Paths in, J. E. Jones, 310; Coke Oven, The Application of, to the Synthesis of Ammonia, G. Claude, 310; Illuminating, Poisoning by, 293; Industry, The, Dr. J. S. G. Thomas, 350; Ionisation and Resonance Potentials, Prof. W. A. Noyes, 482; Manufacture, Distribution and Use: Teachers' Notes for Lessons, with Blackboard Illustrations. Second edition, 250; Process, Early History of the, D. Brownlie, 512; The Distribution of, W. Hole. Fourth edition, 350; Undertakings: The Administration and Finance of, with special reference to the Gas Regulation Act, 1920, G. Evetts, 350
Gaseous: Combustion at High Pressures, Pt. III., Prof. W. A. Bone, D. M. Newitt, and D. T. A. Townend, 622; Mixtures: Explosions of, A Study of, Prof. A. P. Kratz and C. Z. Rosencrans, 545; The Pressures of, Dr. I. Masson and L. G. F. Dolley, 622; Viscosity measured by the Interferometer U-tube, Dr. C. Barus, 763
Gases: Adsorption of, by Solids and the Thickness of the Adsorbed Layer, M. H. Evans and H. J. George, 206; A New Equation of State for, A. Leduc, 691
Gasoline in the United States, 720
Gasterosteus acuteatus, The Comparative Toxicity of Various Acids for Fishes, Mlle. F. Gueylard and M. Duval, 35
Gastrioceras, The Occurrence of, at the Irwin River Coalfield, W.A., and a Comparison with the So-called Paralegoceras from Letti, D.E.I., W. S. Dun and Sir Edgeworth David, 311
Gasworks: Chemistry, Modern, Dr. G. Weyman, 350; Recorders: Their Construction and Use, Dr. L. A. Levy, 350
Gaumont Loud-speaking Telephone, The, L. Gaumont, 96
Geber, The Identity of, E. J. Holmyard, 191; Prof. J. R. Partington, 219
Gelatin: The Action of, upon Concentration Cells, R. Audubert, 520; and Glue, The Chemistry and Technology of, Dr. R. H. Bogue, 456
Gelatine Films, Amount of the Displacement in, shown by Precise Measurements of Stellar Photographs, C. Davidson, 169
Gels: Diffusion in, The Indicator Method for the Determination of Coefficients of, with special reference to the Diffusion of Chlorides, W. Stiles, 419; The Nature of, Dr. S. C. Bradford, 200
General Electric Co., Cleveland, Ohio: Abstract Bulletin of the Research Laboratory of the Lamp Works, 545; London, Research Laboratories, Official Opening of the, 298
Genetics, Biometry and, Prof. R. Pearl and others, 513
Geneva University, honorary doctorates conferred on Prof. A. C. Seward and D. W. Freshfield, 828
Genoa University, Dr. R. Issel appointed professor of zoology in, 205
Geodesy, Institute of, in Finland, Report of the, 820
Geodetic Levelling, 7
Geographical Factors, The Influence of, on the Agricultural Activities of a Population, Sir John Russell, 64
Geography: Business, E. Huntington and Prof. F. E. Williams, with the co-operation of Prof. R. M. Brown and L. E. Chase, 531; Commercial, Handbook of, G. G. Chisholm. New edition, 77; The Pupils' Class-book of, the Americas, E. J. S. Lay, 427; in Business Life, Prof. Tower, 64; in Education, 64; Test, A, in Secondary Schools, E. J. Bradford, 65
Geological: Society, awards of the, 93; election of officers and council of the, 407; election of foreign members and foreign correspondents, 716; Survey of Great Britain, Summary of Progress of the, and the Museum of Practical Geology for 1921, with Report of the Geological Survey Board and Report of the Director, 664
Geologie in Tabellen für Studierende der Geologie, Mineralogie, und des Bergfachs, der Geographie und der Landwirtschaft, Prof. K. Andrée. Erster, Zweiter und Dritter Teil, 630
Geologische Rundschau, the, 822
Geology: C. I. Gardiner, 876; Astronomy and, The Borderland of, Prof. A. S. Eddington, 18; Engineering, Elements of, Profs. H. Ries and T. L. Watson, 732; Physical Science on, The Bearing of Some Recent Advances in, Prof. J. Joly, 726; and the Ice-cap in Northern Greenland, 512; in War, 873; of the London District, The, H. B. Woodward. Second edition, revised, by C. E. N. Bromehead; with Notes on the Palæontology by C. P. Chatwin, 251; of the Schists of the Schichallion District of Perthshire, The, E. M. Anderson, 485
Geology's Debt to the Mineral Industry, Dr. W. G. Miller, 482
Géometrie non-Euclidienne, Introduction à la, Dr. A. MacLeod, 11
Geometry: Elementary, The Teaching of, 271; Postulational, and Physics, Prof. O. Veblen, 482; School, Sequence in, 277
Geophysics, Antarctic, 897
Geophysik, Zeitschrift für angewandte. Unter ständiger Mitarbeit zahlreicher Fachgenossen. Herausgegeben von Dr. R. Ambronn, Vol. I., Part I., 145

German Book Prices, Prof. D. H. Peacock, 362
Germanium, The Isotopes of, Dr. F. W. Aston, 771
Germany, The Compulsory Teaching of English in, Plea for, Prof. A. Brandt, 518
Giardias Living in Man and other Animals, R. W. Hegner, 858
Glacial Succession in the Thames Catchment-basin, Rev. C. Overy, 242
Glands in Health and Disease, Dr. B. Harrow, 694
Glasgow, Royal Technical College: Report for 1921–22, 33; Dr. S. P. Smith appointed professor of electrical engineering, 586
Glass: Bubbles in, Analysis of, J. W. Ryde and R. Huddart, 691; Melting and Working of, Effect of Boric Oxide on the, F. W. Hodkin and Prof. W. E. S. Turner, 420; The Electrical Conductivity of, L. L. Holladay, 375; The Diphasic Nature of, as shown by Photo-elastic Observations, Prof. L. N. G. Filon and F. C. Harris, 725; Containers for Foodstuffs, R. L. Frink, 613; Industry, British, Directory for the, 510; -melting, A New Method of, A. Ferguson, 830; Technology, Society of, election of officers and council, 681
Glasses, Boric Oxide-containing, Some Physical Properties of, Violet Dimbleby, S. English, and Prof. W. E. S. Turner, 420
Glassware, The Durability of, A Rapid Method of Testing, H. S. Blackmore, Violet Dimbleby, and Prof. W. E. S. Turner, 519
Gliding: Flight, Prof. C. Runge, 62; Record, A. Maneyrol, 25; Lieut. Thoret, 58
Glutathione, The Oxidation of Reduced, and other Sulphydryl Compounds, M. Dixon and H. E. Tunnicliffe, 274
Glycogen, The Composition of, Samec and V. Isajevič, 796
Glyoxal, The Ultra-violet Spectrum of, A. Luthy, 867
Gold Coast Survey, The, 166
Gold-headed Cane, The, Dr. W. Macmichael. New edition, 281; A New Edition, with an Introduction and Annotations by G. C. Peachey, 700
Golden Bough: The, a Study in Magic and Religion, Sir James George Frazer. Abridged edition, 658
Golgi: Bodies in Protozoa, Stages of, Miss S. D. King and Prof. J. B. Gatenby, 326; The Reticular Apparatus of, The Nature and Function of, M. Sánchez y Sánchez, 103
Goligher Circle, The, May to August 1921 (Psychical Research), Dr. E. E. Fournier d'Albe, 139
Goloubatz Fly, New Researches on the, J. Georgévitch, 832
Gondwana System in Central India, Discovery of Marine Beds at the Base of the, 550
Gough Island, The Flora of, E. G. Baker, 206
Government Administration, Science and, Lt.-Col. M. O'Gorman, 521
Gravitation: and Light-pressure in Nebulæ, Dr. J. H. Jeans, Prof. F. A. Lindemann, 806; Can, Really be absorbed into the Frame of Space and Time? Sir Joseph Larmor, 200
Great and Small Things, Sir Ray Lankester, 800
Greek Geometry, with specific reference to Infinitesimals, Sir T. L. Heath, 152
Green: Flash at Sunset, The, J. Evershed, 13; Ray, The, Instr. Lt.-Commdr. F. W. Shurlock, 269
Greenland: A Summer in, Prof. A. C. Seward, 99, 284; North-west, L. Koch's Expedition to, 751
Greenwich, Royal Observatory, Annual Visitation, 789
Gregorian Calendar, Greece adopts the, D. Eginitis, 546
Griffithides convexicaudatus Mitch., Two New Trilobites and Note on, J. Mitchell, 135
Growth, Rate of, Some Experiments on, in a Polar Region (Spitsbergen), and in England, Dr. J. H. Orton, 146
Guthrie Lecture, The, Dr. J. H. Jeans, 761
Guy's Hospital, gift to for research, by Ashton and Parsons, Ltd., 25
Gymnosperms, The Vacuome in the Pollen Grains of, P. Dangeard, 554
Gypsies of Turkey, The, Prof. W. R. Halliday, 160
Gypsum, The Dehydration of, P. Jolibois and P. Lefebvre, 763
Gyromagnetic Ratio, The Magnitude of the, Prof. O. W. Richardson, 205
Haber Process, The, Prof. F. Haber, 101
Hadfields, Ltd., the Steel Works of, Visit of the Prince of Wales, 759, 783
Hæmoglobin: Adsorption and: Sir W. M. Bayliss, 666; W. E. L. Brown, 881; Prof. A. V. Hill, 843; J. Barcroft, N. K. Adam, 844; Content and Surface of Red Blood-cells, Relation between, Dr. E. Gorter, 845; Rate of Oxidation and Reduction of, Measurements of the, Dr. H. Hartridge and F. J. W. Roughton, 242; The Measurement of the Rates of Oxidation and Reduction of, Dr. H. Hartridge and F. J. W. Roughton, 325
Hæmolysis, The Inhibitory Effect of Blood Serum on, E. Ponder, 450
Hafnium: and New Zealand Sand, Dr. A. Scott, 598; and Titanium, Sir T. E. Thorpe, 252; W. L. Fox, 429; proposed name for a New Element, Dr. D. Coster and Prof. G. Hevesy, 79; On the New Element, Dr. D. Coster and Prof. G. Hevesy, 182, 252; On Celtium and, Dr. D. Coster and Prof. G. Hevesy, 462; The Optical Spectrum of, H. M. Hansen and S. Werner, 322
Hail and Sleet in Meteorological Terminology, R. Giacomelli, 100
Hall Effect, A Theory of the, and the Related Effect for Several Metals, E. H. Hall, 555
Hansen Prize, The, awarded to Dr. E. J. Allen, 509
Hardness and Penetration: A. S. E. Ackermann, 17; Experiments on, E. Mardles, H. O'Neill, 116
Hardwoods, A Method of Identification of Some, M. B. Welch, 311
Hawaiki: The Original Home of the Maori, with a Sketch of Polynesian History, S. P. Smith. Fourth edition, 736
Hayden Memorial Gold Medal, awarded to Prof. A. Lacroix, 126
Hay Fever, 812
Haze on Derby Day—June 6, Dr. J. S. Owens, 848
Head-hunting in Papua, E. B. Riley, 410
Heape and Grylls Rapid Cinema, The, W. Heape, 881
Hearing, The Resonance Theory of, Sir James W. Barrett, G. Wilkinson, 396; Prof. H. E. Roaf, 498
Heart, The, as a Power-chamber: a Contribution to Cardio-Dynamics, Dr. H. Sainsbury, 314
Heat: W. J. R. Calvert, 216; Action of, on Kaolins, Clays, etc., Black Pottery, A. Bigot, 383; and Heat Engines: The Theory of, Notes and Examples on, J. Case. Second edition, 596; Modern Practice in, T. Petrie, 596; Loss of, from Surfaces, Dr. E. Griffiths and A. H. Davis, 62; The Mechanical Equivalent of, Prof. T. H. Laby, 877; Transmission, 12
Heaviside, Proof of a Theorem due to, Prof. H. A. Lorentz, 36
Hebrew Exodus from Egypt, Dating the, Dr. H. R. Hall, A. Weigall, 753
Helium: α-particles in, Tracks of, Prof. D. M. Bose and S. K. Ghosh, 463; Band Spectrum of, The Structure of the, II., W. E. Curtis, 418; in Airships, Capt. G. A. Crosco, 887; in the United States, Dr. R. B. Moore, 88; Neutral, The Spectrum of: Dr. L. Silberstein, 46; Prof. W. M. Hicks, 146; The Crossed-orbit Model of, its Ionisation Potential, and Lyman Series, Dr. L. Silberstein, 567
Helminthology, Journal of, No. 1, 683
Herapath's Artificial Tourmalines, Dr. M. Nierenstein, 291
Herbals, The Old English, Eleanour Sinclair Rohde, 143
Herbert Pendulum Hardness Tester, The, 583
Hermit-crab, The, and the Anemone, A. T. Watson, 464
Hertzian Waves over Long Distances, The Propagation of, G. Bigourdan, 691
Hesperopithecus, The Tooth of, Profs. Broili and Schlosser, 406
Heterosomata (Flat-fishes) of South Africa, The, C. von Bonde, 796
High-altitude Mountaineering, G. I. Finch, 480
Highlands, The, with Rope and Rucksack, Dr. E. A. Baker, 800
Highway Engineering and Highway Transport Education Problems, 34
Hilger Microscope Interferometer, The, F. Twyman, 623
Hill Pastures, Productivity of, J. P. Howell, 373
Himalayan Mountain System in South-east Asia, The, Prof. J. W. Gregory, 444

Hindu Pantheon, Music and the, Lily Strickland-Anderson, 555
Hinduism according to Muslim Sufis, M. A. Wali, 656
Hippuris vulgaris Linn., The Structure of the Fruit of, Dr. A. B. Rendle, 623
"Holderness Harpoons," The British Association and the, 645
Holiday Courses, List of, 652
Hollow Steel Bodies, Variations of Capacity accompanying the Thermal Treatment of, A. Portevin, 554
Holtzhuisbaaker Spring, Cradock, T. Stewart, 623
Hong-Kong: University: Dr. J. S. Anderson appointed professor of medicine, 552; gift to, by Sir Catchick Paul Chater, 652; Weather at, during 1922, T. F. Claxton, 894
Hookworm Disease, proposal to reduce expenditure on the combat of, 578
Hopkinson Pressure Bar, Experiments with the, J. W. Landon and H. Quinney, 866
Hormones, 694
Hornblende and Bytownite from Hypersthene Gabbro, Black Bluff, near Broken Hill, Ida Brown, 311
Horsley, Victor, Memorial Lecture, Sir E. Sharpey Schafer to deliver the first, 125
House-sparrow, Curious Habit of a, W. Muir, 681
Hull: Municipal Museum, Publications of the, T. Sheppard, 406; Catalogue of the Coin Collection at, W. Sykes, 616
Human: Behaviour in Society, The Neurological Basis of, W. J. Perry, 654; Character, H. Elliot, 174; Heads carved in Steatite from Sierra Leone, M. Addison, 170; Inheritance, The Treasury of, Vol. II.: Anomalies and Diseases of the Eye. Nettleship Memorial Volume. Part I: J. Bell. With a Memoir of Edward Nettleship by Dr. J. B. Lawford, 492
Humanism in Technical Education, Sir Thomas Holland, 376
Humboldt Current, The, R. C. Murphy, 199
Humic and Fatty Materials in the Soil, Estimation of, by means of Pyridine, M. Piettre, 763
Hydra, Green and Colourless: Experimental Production of, W. Goetsch, 484; Prof. S. J. Hickson, 601
Hydrates of Gases, A Class of Unstable Hydrates known as, A. Bouzat, 243
Hydration of the Dialkylethioryl-carbinols, etc., R. Locquin and S. Woureng, 383
Hydrautomat, The, 306
Hydrocyanic Acid, A Polymer of, C. Bedel, 207
Hydrogen: and Chlorine, Active, Prof. Y. Venkataramaiah, 583; Active: by Electrolysis, Prof. A. C. Grubb, 671; by the Action of an Acid on a Metal, Prof. A. C. Grubb, 600; Molecule, A Static Model of the, Prof. H. S. Allen, 830; The Critical and Dissociation Potentials of, A. R. Olson and G. Glockler, 868; Ion Concentration, Prof. A. V. Hill, 434; of Sea Water, The, Dr. W. R. G. Atkins, 132; of the Soil in relation to the Flower Colour of *Hydrangea hortensis* W., and the Availability of Iron, Dr. W. R. G. Atkins, 487
Hydrohepatosis, A Condition analogous to Hydronephrosis, P. D. McMaster and P. Rous, 554
Hydromechanics, Mathematics of, Some Extensions in the, R. S. Woodward, 554
Hygiene of the Great War, 626
Hygroscope, An Improved, Negretti and Zambra, 269

Ice: Age, Man and the, Prof. W. J. Sollas, 332; in Glaciers, Clear, a New Theory of the Blue Colour of, Prof. C. V. Raman, 413; Patrol Service in North Atlantic, Lt. E. H. Smith, 617
Iceland, Norway and, An Interesting Contrast, 514
Igneous Rocks of the Torquay Promontory, The Petrography and Correlation of the, W. G. St. J. Shannon, 134
Illuminating Engineering, Training in, C. E. Greenslade, J. E. S. White, and others, 157
Image: A Permanent, on Clear Glass, E. Robinson, 569; Dr. J. W. French, 570; Dr. T. J. Baker, 743
Imperial: Botanical Conference, forthcoming, 371; College of Science and Technology, opening of the new Botany Building (Plant Technology), 295; Institute, appointment of a committee to investigate the position of the, 230; Mineral Resources Bureau, Report for 1922, 821
Inca Land: Explorations in the Highlands of Peru, Prof. H. Bingham, 665
Incandescent Lighting, S. I. Levy, 392
Index Generalis, published under the direction of Dr. R. de Montessus de Ballore, 425
Indexing of Biological Literature, Dr. J. R. Schramm, 508
India: Agricultural Progress in, D. R. Sethi and others, 584; Botanical Survey of, Report for 1921–22, Lt.-Col. A. T. Gage, 547; conference of veterinary authorities in, 612; Criminal Tribes of, Commissioner Booth Tucker, 410; Destitution in, Sir M. Visvesvaraya, 413; Fall of a Meteorite in, 266; Fleas and Plague in, Rothschild, 302; Happy, as it might be if guided by Modern Science, A. Lupton, 180; Meteorology in, Dr. G. T. Walker, 28; Modern, Clash of Ideals in, Earl of Ronaldshay, 581; North-west, Probable Weather in, Dr. G. T. Walker, 338; Postal and Telegraph Work in, G. R. Clarke, 891; Report of the Survey of, Col. Ryder, 515; Research in, The Organisation of, 797; The Oldest Christian Tomb in, Mesrovb Seth, 339; The Population of, J. T. Marten, 786; The Upper Air in, J. H. Field, 269
Indian: Charophyta, Notes on, J. Groves, 726; Eclipse Expedition, 1922, The, J. Evershed, Dr. W. J. S. Lockyer, 862; Industries and Labour, Journal and Bulletins of, to be discontinued, 477; Irrigation, Dr. B. Cunningham, 388; Science Congress, The, Prof. C. V. Raman, 413; Sketches, A Lost Collection of, Lt.-Col. H. H. Godwin-Austen, 845; Tribes of California, The, A. L. Kroeber, 339
Indo-Europeans, The Home of the, Prof. H. H. Bender, 111
Induction Motors as Synchronous Machines, S. V. Ganapati and G. R. Parikh, 161
Industrial: Fatigue Research Board, Third Annual Report, 898; The Problem of, Miss Mona Wilson, 616; Force: A New, the Utilisation of the Heat furnished by Thermal Springs, J. Dybowski, 488; Lighting and the Prevention of Accidents, L. Gaster, 715; Paints and the Health of the Worker, 685; Psychology and Coal Mining, 718; Science, Fact and Phantasy in, C. F. Cross, 585
Industry: Administration in, Training for, Capt. H. Riall Sankey, 157; Labour and Science in, 385; Prof. F. Soddy, 497; F. S. M., 498
Infant Mortality, Dr. H. T. Ashby. Second edition, 530
Influenza: Epidemic, The Alleged Discovery of the Virus of, Drs. P. K. Olitsky and F. L. Gates, 193; The Alleged Discovery of the Cause of, 336
Infusoria, The Nutrition of the, A. Lwoff, 554
Inoculation of the Herpetic Virus, in the Genital Organs of the Rabbit, C. Levaditi and S. Nicolau, 172
Insect Pests and Fungous Diseases of Farm Crops, A. Roebuck, 804
Insects affected by Changes of Air Pressure, Commdr. H. Young, 409
Installations électriques industrielles: Installation—Entretien—Contrôle, R. Cabaud, 427
Institution: of Electrical Engineers, the Faraday medal of the, awarded to Sir Charles Parsons, 266; of Heating and Ventilating Engineers, J. Watson elected president of the, 300; of Mechanical Engineers, gift to, by W. H. Allen, 449
Insulated and Refrigerator Barges for the Carriage of Perishable Foods, 840
Insulin: Dr. H. H. Dale, 253; Diabetes, and Rewards for Discoveries, Sir W. M. Bayliss, 188; Effect of, upon Blood Sugar Concentration, L. B. Winter and W. Smith, 810; the sale of, appointment of a committee on, 578
Intellectual Regimentation, Sir Michael Sadler, 245
Intelligence Tests and School Reorganisation, L. M. Terman and others, 840
Interferometer: A Universal, Dr. A. E. H. Tutton, 725; The, in Astronomy, Prof. A. S. Eddington, 572
Intermetallic Compound, An Example of Polymorphism in an, D. Stockdale, 762

Intermittent Pressure by Boiling Water, The Production of an, C. R. Darling, 830
Internal Combustion: Engine, The: H. R. Ricardo. Vol. I.: Slow-speed Engines, 43; a Text-book for the Use of Students and Engineers, H. E. Wimperis. Fourth edition, 320; Motors, The Theory of, M. Brutzkuo, 903
International: Astronomical Union, The, 101; Latitude Observatory at Ukiah, California, U.S., appropriation for the, 476; Meteorological Committee, Report of the Eleventh Ordinary Meeting, 26
Intersexuality, Studies in, I., F. A. E. Crew, 653
Intestinal: Disinfection, The Possibility of Realising, A. Lumière, 383; Parasite of Man, An, 379
Invariants Intégraux: Leçons sur les, Cours professé à la Faculté des Sciences de Paris, Prof. E. Cartan, 217
Iodine, A Hydrate of, P. Villard, 867
Iodosalicylic Acids, The, P. Brenans and C. Prost, 903
Ionic Mobilities in Air and Hydrogen, J. J. Nolan, 35
Ionised Gas, The Opacity of an, J. Q. Stewart, 186
Ions in Air, Experiments on Large, J. J. Nolan and J. Enright, 794
Ireland, Geological Survey of, Catalogue of Maps, Memoirs and Sections published by the, 892
Iridescent Colour, Studies of, and the Structure producing it: Lord Rayleigh, 346; IV., Iridescent Beetles, Lord Rayleigh, 418
Irish Sea Plankton, 448
Iron: and Nickel, Alloys of, Constitution of the, Dr. Hanson and J. R. Freeman, jun., 861; and Steel: Institute, the Bessemer gold medal of the, awarded to Dr. W. H. Maw, 300; the Metallurgy of, Advances in, Sir Robert Hadfield, 232; Carbide of, The Etching Properties of the α-and β-forms of, F. C. Thompson and E. Whitehead, 762; The Corrosion of, in the Presence of Iron Sulphide, R. Stumper, 762; The Demagnetisation of, by Electro-magnetic Oscillations, S. K. Mitra, 727; Total, The Histochemical Detection of, in Tissues by the Method of Incineration, A. Policard, 692
Irrigation in India, Triennial Review of, 1918–1921, 388
Ismaili Sect of Islam, The, W. Ivanov, 339
Isoetaceæ, The, N. E. Pfeiffer, 443
Isopod, New, from Central Australia, Prof. C. Chilton, 823
Isotopes: M. de Broglie, 510; The Separation of, J. Kendall and E. D. Crittenden, 763
Isotopic Ions, Separation of, J. G. Pilley, 848
Italian Society for the Advancement of Science, The, 685

Jades of Middle America, The, H. S. Washington, 36
Japanese: Journal of Chemistry, the, 614; *Journal of Physics*, the, 478; Marine Triclads, T. Kabouraki, 753; Plant Products, Chemistry of some, Y. Asahina, 823
Jellies, Deformations of, by the Action of an Electric Current, F. Michaud, 727
Jelly, The Rigidity of, F. Michaud, 35
Jenner: Edward, 69; Centenary Celebration in Paris, 156; pictures and relics, exhibit of, 230
Jupiter: New Observations of, F. Sargent, 27; The Eighth Satellite of, Prof. E. W. Brown, 546; The Great Red Spot on, W. F. Denning, 233; The Planet, F. Sargent, 580
Jupiter's Satellites, The Theory of, Prof. de Sitter, 717

Kahn, Albert, Travelling Fellowship, the, awarded to W. Randerson, 864
Kammerer's, Dr.: Alytes, Dr. W. Bateson, 878; Experiments, Prof. E. W. MacBride, 841
Kansou Earthquake, The: Determination of the Epicentre, Mlle. Y. Dammann, 588
Kaolins, Clays, etc.: Action of Heat on, A. Bigot, 171; Colloidal Plasticity, A. Bigot, 831
Kent's Cavern Anthropology and the Ice Age, H. J. Lowe, 95
Kew, Royal Botanic Gardens: damage from smoke in the, 679; exhibit of abnormal growths taken from trunks, etc., of trees and shrubs, 299; exhibition of funeral wreaths, etc., from Egyptian tombs, 266; exhibit of sports requisites, 476
Kincardineshire, the late G. H. Kinnear, 144
Kinematograph Studio Technique, L. C. Macbean, 427
King's English, the, 490
Knotted Curves, A Lemma on Systems of, J. W. Alexander, 764
Knowledge, For the Diffusion of, 10
Krypton: and Argon, The Hydrates of, R. de Forcrand, 310; and Xenon, The K Absorption Discontinuity of, M. de Broglie and A. Lepape, 903; the Electrons in, Critical Velocities of, and the Production of the Spectra of this Gas, G. Déjardin, 554

Labour and Science in Industry, 385
Lactic Fermentation, Influence of Copper on the, M. Fouassier, 451
La Force motrice électrique dans l'Industrie, E. Marec, 494
Lamba Language, The Grammar of the, C. M. Doke, 460
Lamp Oil and Alcohol containing a High Percentage of the Latter, Utilisation (in a Motor) of a Mixture of, M. Dumanois, 831
Land Molluscs, Dr. N. Annandale, 656
Langley Aeroplane, The, 25
Laramie Problem of the Rocky Mountain, The, F. H. Knowlton, 548
L'Arc électrique, M. Leblanc fils, 805
Larch Chermes (*Cnaphalodes strobilobius* Kalt.), Researches upon the, E. R. Speyer, 274
Lea Valley, The late Glacial Stage of the (third report), S. H. Warren, 419
Lead: and Turpentine in the Professional Pathology of Painters, The Rôles of, F. Heim, E. Agasse-Lafont, and A. Feil, 243; in Britain, Production of, Prof. H. Louis, 512; The Hardness and Spontaneous Annealing of, A. L. Norbury, 762; The Vapour Pressure of. I., A. Egerton, 381
League of Nations Committee on Intellectual Co-operation, work of the, Prof. K. Bonnevie, 829
Leeds University: Report on the Textile Industries and Colour Chemistry Departments of, 205; Prof. Smithells re-appointed Pro-Vice-Chancellor; J. Robb appointed district lecturer in agriculture; Dr. W. H. M. Telling to be professor of therapeutics in the department of medicine, 307; conferment of an honorary degree upon E. F. L. Wood, 380; agreement with Basle University for a scheme of mutual recognition of courses and examinations, 449; conference on full-time education for boys and girls and the choice of subjects for school examinations, 586; course of training in printing; grants from the County Borough Councils of Dewsbury and Halifax; Dr. R. W. Whytlaw-Gray appointed professor of chemistry, 586; a War Memorial by E. Gill, 651; Report for 1921–22, 688; grant from the Huddersfield Town Council; appointments, 900
Leibniz, Some Problems in the Philosophy of, L. J. Russell, 726
Leicester, University College, Dr. Ethel N. Miles Thomas appointed lecturer in botany and zoology at, 518
Leodicidæ, Reproduction in the, Prof. A. L. Treadwell, 28
Lepidoptera, Spermatogenesis of the, Prof. J. B. Gatenby, 568; H. G. Cannon, 670
Leprosy, Treatment of, Sir Leonard Rogers, 858
Leptoplana, A New Gregarine Parasite of, Prof. B. L. Bhatia, 116
Leucocytic Secretions, A. Carrel, 555
Leucotermes lucifugus, A New Appearance of, P. Lesne, 832
Lhota Nagas, The, J. P. Mills. With an Introduction and Supplementary Notes by J. H. Hutton, 282
Liberal Education in Secondary Schools, 862
Life: Contingencies, E. F. Spurgeon, 769; in the Southern Hemisphere, The Distribution of, and its Bearing on Wegener's Hypothesis, K. H. Barnard and others, 131
Light: Elements, The, and the Whole Number Rule, Dr. F. W. Aston, 739; in Gases and Liquids, The Theory of Dispersion and Scattering of; The Complex Anisotropic Molecule in Relation to, Dr. L. V. King, 667; in Paris and its Neighbourhood, The Loss of, L. Besson, 207; Projection of, in Optical Lanterns

and Kinema Apparatus, 408; -Quanta, The Nature of, H. Bateman, 567; Sensitiveness, Vision and, J. P. O'Hea, 705; The Action of, on Growth, E. Wollman and M. Vagliano, 904; The Diffraction of, by the Eyelashes, R. Vladesco, 728; The Scattering of: by Liquids, Prof. C. V. Raman and K. S. Rao, 412; by Organo-sols and Gels of Cellulose Acetate, E. W. J. Mardles, 170; in Fluids at Low Temperatures, K. S. Rao, 413
Lighting, Natural, Survey of, P. J. and J. M. Waldram, 476
Lily, the White: Nature of the Secretion of the Sterinoplasts of, M. Mirande, 451, 488
Lime in the West Indies, Ligneous Zonation and Die-back in the, T. G. Mason, 831
Limiting Equality, The Definition of, Prof. G. H. Bryan, 183
Limulus, Circus Movements of, W. H. Cole, 555
Linear Differential Equations, Solutions of Systems of Ordinary, by Contour Integrals, Prof. W. McF. Orr, 762
Linen Weaving, Fine, Efficiency of, H. C. Weston, 442
Linné, Carl von, Bref och Skrifvelser af och till, med understöd af Svenska Staten utgifna af Uppsala Universitet, 594
Linnean: Correspondence, 594; Society, election of officers and council, 751; Dr. J. I. Briquet elected a foreign member, 680
Liquid: Mixtures, The Separation of, by Combined Distillation and Atmolysis, E. and R. Urbain, 207; State, The Nature of the, Prof. C. V. Raman; Sir William Bragg, 428
Liquids: The Molecular Ælotropy of, Prof. C. V. Raman, 555; The Purification of, by the Simultaneous Action of Centrifugal Force and the Electric Field, A. Marx and J. Rozières, 795; the Viscosity of, A Theory of, Prof. C. V. Raman, 532, 555, 600; R. M. Deeley, 774
Lisbon Academy of Sciences, Sir E. Wallis Budge elected a foreign correspondent associate of the, 855
Lithium Carbide and Hydride, A. Guntz and Benoit, 648
Lithuania University, Issue of a Bilingual Calendar, 418
Litre, the, Resolution of the American Metric Association respecting, 231
Liverpool: Observatory, Bidston, Report of the, W. E. Plummer, 412; University: opening of new chemical laboratories, 552; Department of Geology, New Gift from Sir William Herdman, 723
Livingstone, David, Centenary Medal for 1923, the, awarded to Dr. T. Griffith Taylor, 891
Logarithms to Seven Places of Decimals, A New Manual of, edited by Dr. Bruhns. Thirteenth edition, 320
London: cleaner air for, 509; University: increase of grant to the Marine Biological Association; conferment of doctorates, 168, 417, 449, 552, 828, 901; Dr. E. E. Turner appointed demonstrator in the Chemical Department of the East London College, 168; grant to Rev. F. J. Wyeth; resignation of Prof. M. J. M. Hill; Universities and the Ph.D. degree; conferment upon A. E. Clayton of the degree of D.Sc. (Eng.), 307; Prof. A. V. Hill appointed Jodrell professor of physiology; W. J. Perry appointed reader in cultural anthropology; Dr. B. Malinowski appointed reader in social anthropology, 449; conferment of a doctorate on Miss K. H. Coward, 485; Prof. L. Bairstow appointed Zaharoff professor of aviation at the Imperial College of Science and Technology; Dr. C. L. Boulenger appointed professor of zoology at Bedford College; Miss B. E. M. Hosgood appointed reader in geography at Bedford College, 723; Dr. J. Marshall appointed reader in mathematics at Bedford College, 724; College Committee, Annual Report of the, 761; appointments, 900-901
Longitudes, Bureau des, Annuaire pour l'an 1923 publié par le, 144
Lorentz, H. A. (Scientific Worthies, XLII.), Sir Joseph Larmor, 1
Lorentz's Equations and the Concepts of Motion, Prof. R A Sampson 795
Loroglossin in Native Orchids, The Presence of, P. Delaunay, 451
Loughborough College, Presentation Day of, 418
Low-resistance Circuits, Inductively Coupled, Prof. C. H. Lees, 346
Lubrication: and Lubricants, J. H. Hide, 392; The Latent Period in, Ida Doubleday and W. B. Hardy, 182
Luminescent Chemical Change, A, W. V. Evans and R. T. Dufford, 481
Luminosity of some Animals in the Gangetic Delta, B. Prashad, 832
Lunularia cruciata, The Fungus present in, Miss W. Ridler, 274

M Series of the Elements, The, A. Dauvillier and L. de Broglie, 35
Machine: Construction and Drawing, A Text-book of, H. E. Merritt and M. Platt, 737; Shop Mathematics, G. Wentworth, D. E. Smith, and H. D. Harper, 805
Madras, the Presidency of, Flora of, J. S. Gamble. Part 5, 631
Magnesium, The Rapid Estimation of, in a Single Drop of Sea-water, G. Denigès, 35
Magnet, A Levitated, F. H. Glew, 669
Magnetic: Bodies, Feebly, Susceptibility of, as affected by Tension, Prof. E. Wilson, 241; Disturbance of March 24-25, The, Rev. A. L. Cortie, 534; Field, Distribution of the, and Return Current round a Submarine Cable carrying Alternating Current, Pts. I. and II., C. V. Drysdale and S. Butterworth, 793; Measurements: in Brittany, C. Maurain, 520; in Normandy, C. E. Brazier, 588; in the Paris Basin, L. Éblé, 903; Observations at Batavia, 29; Phenomena in the Region of the South Magnetic Pole, Dr. C. Chree, 866; Recording Drum for Electric Relays, Dr. N. W. McLachlan, 617
Magnetism, Theories of, Dr. A. E. Oxley, 54
Maithili Dramas of the Seventeenth and Eighteenth Centuries, K. G. Sinha, 555
Makdougall-Brisbane Prize, The, awarded to Prof. W. T. Gordon, 681
Maladies parasitaires des plantes, Les (Infestation-Infection), M. Nicolle et J. Magrou, 77
Malay: Peninsula, The Flora of the, H. N. Ridley. Vol. 1: Polypetalæ, 6; The Writing of, C. H. Pownall, 581
Malta: and Gozo, Ethnology of, L. H. D. Buxton, 858; Flints in, Miss M. A. Murray, 783
Mammifères fossiles de Tarija, Prof. M. Boule avec la collaboration d'A. Thevenin, 699
Man: and the Ice Age: Prof. W. J. Sollas, 169, 332; as a Geological Agent: An Account of his Actions on Inanimate Nature, Dr. R. L. Sherlock, 352; as an Agent in Geographical Change, Dr. R. L. Sherlock, 340; Biology of, Prof. K. Pearson, J. S. H., 809; Chromosomes in, Dr. T. S. Painter, 786; The Animal, Prof. W. M. Smallwood, 78
Man's Posture: its Evolution and Disorders, Sir Arthur Keith, 476
Manchester: Literary and Philosophical Society, election of officers and council, 645; Municipal College of Technology, the coming of age of the, 724; Museum: Gift to, by C. Heape, 855; Prof. G. H. Carpenter appointed Keeper of the, 204; University: proposed institution of an honours school of geography, 196; Dr. J. C. M. Brentano appointed lecturer in physics; H. W. Baker lecturer in engineering; A. D. Ritchie lecturer in biological chemistry, 240; D. C. Henry appointed lecturer in colloid chemistry and to take charge of the Graham Research Laboratory; N. B. Maurice recommended for the degree of Ph.D., 307; resignation of R. S. Adamson; C. R. Christian appointed temporary demonstrator in pathology; honorary degrees to be conferred on Prof. N. Bohr, Prof. F. G. Hopkins, and W. B. Worthington, 418; resignation of the chancellorship of, by Lord Morley of Blackburn; F. Fairbrother appointed lecturer in chemistry, Dr. D. S. Sutherland clinical lecturer in infectious diseases, and Dr. R. Marsden honorary clinical lecturer in tuberculosis, 449; resignations of appointments, 652; L. J. Mordell appointed Fielding professor of pure mathematics; Lord Crawford nomi-

nated as chancellor, 688; approval of the institution of a special diploma in bacteriology, 760; award of doctorates; W. H. Dearden elected Hadfield research scholar at Stockholm, 828; appointments, 901
Maori, The Mind of the, S. H. Ray, 790
Maps, Old, Exhibition of, at Manchester, 196
Marble, Synthetic, Dr. M. Copisarow, 787
Marine: Beds at the Base of the Gondwana System in Central India, Discovery of, 550; Biology, Trieste and, Dr. M. Stenta, 650; Engineering, The Present and Future of, 470; Observer's Handbook, The. Third edition, 701; Works: a Practical Treatise for Maritime Engineers, Landowners and Public Authorities, E. Latham, 285
Market Produce, Pathology of, 516
Marriage Customs in Medieval India, Sir G. Grierson, 647
Marsupialia, The Development of the Hepatic Venous System and the Postcaval Vein in the, M. Tribe, 450
Martini's Equations for the Epidemiology of Immunising Diseases, Dr. A. J. Lotka, 633; Prof. G. N. Watson, 808
Maryland, The Oldest Rocks of, Eleanora B. Knopf and Anna T. Jones, 480
Mass Spectra, Dr. F. W. Aston, 684
Mast and Aerial Construction for Amateurs: Together with the Method of Erection and other Useful Information, F. J. Ainsley, 628
Materials, the Strength of, Further Researches on, Prof. W. E. Dalby, 241
Materie: Der Aufbau der, Drei Aufsätze über moderne Atomistik und Electronentheorie, Prof. Max Born. Zweite Auflage, 109
Mathematical Instruments, Early, in Oxford, 75
Mathematics: and Physical Science in Classical Antiquity, D. C. Macgregor. Translated from the German of J. L. Heiberg (Chapters in the History of Science, II.), 355; for Engineers, W. N. Rose, Part I., 181
Mathematik und Physik: Eine erkenntnistheoretische Untersuchung, E. Study, 565
Matière: dans ses rapports avec la vie: L'Organisation de la, études d'anatomie générale et de morphologie expérimentale sur le tissu conjonctif et le nerf, Prof. J. Nageotte, 72; La Constitution de la, Prof. Max Born. Traduit par H. Bellenot, 109
Matter: A New Theory of, Rev. L. J. Walker, 206; Life, Mind, and God: Five Lectures on Contemporary Tendencies of Thought, Prof. R. F. A. Hoernlé, 770; The Constitution of, 109
Maud, Progress of the, Capt. Wisting, 25
Mazes and Labyrinths: a General Account of their History and Developments, W. H. Matthews, 321
Meaning: The Meaning of, a Study of the Influence of Language upon Thought, and of the Science of Symbolism, C. K. Ogden and I. A. Richards, 566
Meat in Cold Storage, Moulds on, F. T. Brooks and C. C. Hansford, 582
Meats, etc., Preserved, The Examination of, O. Jones, 346
Mechanical Engineers, Institution of. Eleventh Report to the Alloys Research Committee: on some Alloys of Aluminium (Light Alloys), Dr. W. Rosenhain, S. L. Archbutt, and Dr. D. Hanson, 389
Medical: Education: Sir G. Archdall Reid, 50, 324; Prof. W. J. Dakin, 151; in England, Recent Advances in, Sir George Newman, 765; Research Council, Report of the, for the year 1921–22, 421; National Health, etc., 421
Medicine, History of, 281
Megalithic Monuments, Distribution of, O. G. S. Crawford, 602; in England and Wales, Distribution of, W. J. Perry, 442
Melanesia, Essays on the Depopulation of. Edited by Dr. W. H. R. Rivers, 145
Melbourne University, gift to, by the Victorian Chamber of Manufactures, 205
Meldola Medal, The, of the Institute of Chemistry, awarded to Dr. C. K. Ingold, 337
Men like Gods, H. G. Wells, 591
Mendel and Galton, celebration in Boston of the centenary of the birth of, 544
Mendelejeffite, a New Radioactive Mineral, W. J. Vernadsky, 654
Mendelian Genes, The Function of, J. S. Huxley, 286; Prof. E. W. MacBride, 394
Mendelism, International Contributions to, 32
Mensch, Der fossile, E. Werth. Zweiter Teil, 701
Mental: Character and Race, Prof. J. L. Myres and others, 164; Disorders, Certain, which may be regarded as Preventible, Dr. J. M. Moll, 163
Mentone, The Phantom Island of, Prof. G. H. Bryan, 430
Merchant Venturers, Society of, Bristol, Scholarships, 688
Mercurialis perennis, Variations of some Carbohydrate Reserves in, P. Gillot, 904
Mercury: A New Phototropic Compound of, Prof. Y. Venkataramaiah and Bh. S. V. Raghava Rao, 775; and Krypton Radiations, Study of some, with the View of their Applications in Metrology, A. Pérard, 655; Isotopes of, Separation of the, Prof. W. D. Harkins and S. L. Madorsky, 148, 894; The Orbit of, L. Lecornu, 243; The Planet, 60; Photometric Observations of, J. Hopmann, 857; Vapour, Ionisation of, in the Presence of Argon, G. Déjardin, 35
Merkel's Liquid, etc., the Fixation of, R. de Litardière, 832
Mesozoic Iron Minerals of France, Phenomenon of Imprints in the, L. Cayeux, 763
Metal: Crystals, Modification of the Powder Method of Determining the Structure of, E. A. Owen and G. D. Preston, 34; The Thermal Conductivities of: I., Bismuth, Dr. G. W. C. Kaye and J. K. Roberts, 793; Dewar Flasks intended to hold Liquid Air, Further Tests upon, H. Briggs and J. Mallinson, 830; Sols in Non-dissociating Liquids, E. Hatschek and P. C. L. Thorne, 381
Metallic Crystals and Polarised Light, J. H. Shaxby, 431
Metallography: A Text-book of, 249; and Macrography, An Introduction to the Study of, Dr. L. Guillet and A. Portevin. Translated by L. Taverner, 249
Metallurgical Analysis (Non-Ferrous), Tested Methods of, S. Pile and R. Johnston, 356
Metallurgy, Objectives for, H. B. Wrighton, 553
Metals: at High Pressures, The Compressibility of, P. W. Bridgman, 208; Institute of: election of officers and council of the, 372; Journal of the, Vol. 27. Edited by G. Shaw Scott, 112; Vol. 28, 700; Pressure of Fluidity of, A. S. E. Ackermann, 534; The Arc Spectra of, in Various Media and in a Vacuum, St. Procopiu, 310; The Crystallisation of, being a Course of Advanced Lectures in Metallurgy delivered at the Royal School of Mines, Imperial College, under the auspices of the University of London, in February and March 1922, Col. N. T. Belaiew, 876; The Failure of, under Internal and Prolonged Stress: a general discussion held on Wednesday, April 6, 1921, in the Hall of the Institution of Mechanical Engineers. Edited by F. S. Spiers, 250; Thermal and Electrical Conductivities of, Effect of Torsion on the, Prof. C. H. Lees and J. E. Calthrop, 829
Meteor: Photograph of a Bright, Dr. W. J. S. Lockyer, 272; Shower, The April, W. F. Denning, 646
Meteoric Displays, June, W. F. Denning, 785
Meteorite, A Supposed, at Quetta, 510; Slag mistaken for a, at Quetta, G. H. Tipper, 704
Meteorological: Committee to the Air Council, Annual Report of the, 408; Corrections for the Use of Gunners, Notes on, D. Brunt and J. Durward, 107; Disturbance, A, of an Oscillatory Character, Prof. W. G. Duffield, 598; Messages, The New International Code for, 1922, 107; Nomenclature: and Physical Measurements, Sir Napier Shaw, 218; Dr. H. R. Mill, 327; Physics, Prof. V. Bjerknes, 871; Stations at High Latitudes, Sir Frederick Stupart, 754
Meteorology: and the Non-Flapping Flight of Tropical Birds, Dr. G. T. Walker, 886; Catalogue of the Collections in the Science Museum, South Kensington, with Descriptive and Historical Notes and Illustrations, 107; Elementary, A Short Course in, W. H. Pick, 107; in India, Dr. G. T. Walker, 28; in Mysore, N. V. Iyengar, 303; of Scott's Last Journey, The, Dr. G. C. Simpson, 758; of the Gulf of Bothnia, G. Granqvist, Dr. C. J. Ostman, 720; of the South Atlantic, H. H. Clayton, 481; Progressive, Dr. H. R. Mill, 107

Meteors: May, 682; in April, 441; of March 17, W. F. Denning, 479; Perseid, in July 1592, Dr. J. K. Fotheringham, 774; The January, 60
Methyl: Alcohol, Pure, Non-poisonous, Dr. Theiler, 612; Sulphate: Action of, and of Potassium Methyl Sulphate on Monobasic Organic Acids in the Absence of Water, L. J. Simon, 451; The Methylating and Sulphonating Action of, on Phenols in the Absence of Water, L. J. Simon and M. Fréjacques, 554
Methylene Blue, The Reduction of, by Iron Compounds, E. J. Morgan and J. H. Quastel, 653
Methylisopyromucic Acid and a Method of Diagnosis of the Acids of the Sugar Group, L. J. Simon and A. J. A. Guillaumin, 35
Metol, Innocuous, W. F. A. Ermen, 481
Metric System, The American Association and the, 196
Michelson-Morley Experiment, Reconsideration of the, Dr. A. Daniell, 475
Microbic Transmissible Autolysis, Prof. J. Bordet, 339
Microdrili, Glands of the, Dr. J. Stephenson, 61
Micrometric Slide Rule, A, H. J. Denham, 103
Microphonic Flames, Dr. Lee de Forest, 739
Microscope: A New, R. and J. Beck, Ltd., 62; Applications of the, in the Manufacture of Rubber, W. M. Ames, 794; Industrial Applications of the, Prof. F. J. Cheshire and others, 239; A. G. Lowndes, 358; in Palæobotanical Research, Use of the, Prof. A. C. Seward, 653; Lamp, An Electric, Ogilvy and Co., 96; Objectives, Focus Aperture Ratios of, E. M. Nelson, 236
Microscopic Bodies, The Determination of *p*H of, C. F. A. Pantin, 81
Microscopy: in the Examination of Manufactured Paper, S. R. Wycherley, 553; Modern, a Handbook for Beginners and Students, M. I. Cross and M. J. Cole. Fifth edition, revised and rearranged by H. F. Angus, 217
Military Mining, 663
Milk: Characters, Variation and Inheritance of, T. Ellinger, 867; Fat, Comparative Values of Protein Fat, and Carbohydrate for the Production of, E. J. Sheehy, 654; Supply, Pure, The Science and Practice of, 105, 237
Millibar in Aerodynamics, Use of the, Major A. R. Low, 535
Millions Fish, Linked Characters in the, Dr. O Winge, 718
Mimosa, Excitation in, The Conduction of, R. Snow, 237
Mind: -body Problem, The Double-knowledge Approach to the, R. W. Sellars, 67; The Appearance of, J. C. M'Kerrow, 770
Minds, The Contact of, C. D. Burns, 794
Mineral: Deposits in the Development of a Young Country, The Influence of, Dr. E. T. Mellor, 162; Fertilisers, L. Owen, 787
Mineralisation of Histological Sections by Calcination, A. Policard, 655
Minerals: and Rocks, Essentials for the Microscopical Determination of Rock-forming, Dr. A. Johannsen, Dr. J. W. Evans, 143; Concentration of, by Multiphase Magnets, W. M. Mordey, 303; of Economic Importance and Metalliferous Mines in Ireland, Memoir and Map of Localities of, Prof. G. A. J. Cole, 735
Mines: Lighting in, E. Farmer, S. Adams, and A. Stephenson, 341; Safety in, Research Board, appointment of additional members of the, 579
Mining: and Metallurgy, Institution of, Awards of the, 370; Industry of Canada, The, Dr. J. B. Tyrrell, 483
Miocene Cichlid Fish from Haiti, Prof. T. D. A. Cockerell, 858
Mirage: A Remarkable, at Oban, A. Tarn, 440; at Cape Wrath, A Double-Vertical-Reflection, D. Brunt, 222
Mixed and Symmetrical 1-Ethanoic-1-Camphomethanoic Esters and their Saponification Products, The, A. Haller and L. Palfray, 727
Modern Wireless, No. 1, 267
Molecular: and Crystal Symmetry, T. V. Barker, 632; Dr. J. W. Evans, G. Shearer, and W. T. Astbury, 741; Oscillation, Selective Interruption of, A. Fairbourne, 149; R. d'E. Atkinson, 326
Molluscs of South India, The Common, J. Hornell, 12
Molybdenum Ores, Dr. R. H. Rastall, 392
Molybdic Acid, Action of, on the Rotatory Power of the Tartaric and Malic Esters, E. Darmois, 691
Mona Complex, Succession and Metamorphism in the, E. Greenly, 587
Monads, Prof. Wildon Carr's Theory of, Miss H. D. Oakeley, 486
Monochloracetic Acid, A New Method of Preparation of, L. J. Simon and G. Chavanne, 275
Monocotyledons, Supposed Reserve Dextrins of, H. Colin and H. Belval, 832
Monomethylaniline in the Production of Tetryl, The Utilisation of, T. J. Nolan and H. W. Clapham, 654
Moon, Partial Eclipse of the, 301
Moon's Motion, Irregularities in the, W. Child, 682
Moonlight: Brightness of, Colour Temperature and, Dr. W. E. Forsythe, 533; Effect of, on the Germination Seeds, Elizabeth Sidney Semmens, 49
Moray Firth Coast, Photography of the, A. G. Ogilvie, 310
Morbid Fears and Compulsions: their Psychology and Psychoanalytic Treatment, Dr. H. W. Frink, 250
Mosquito Control, Impounding Water for, D. L. van Dine, 374
Motion: Definitions and Laws of, in the "Principia," Sir George Greenhill, 224; of a Fluid in the Field of Velocity produced by a Screw Propeller, the Differential Equations of, Dr. E. Pistolesi, 887
Motors, Testing, An Aerodynamical Arrangement for, P. Dumanois, 383
Moulds, Toxicity of Copper with respect to, R. Dubois, 832
Moulton, Lord, The Life of, H. Fletcher Moulton, 44
Mueller Medal and Fund, Award of the, to J. H. Maiden, 406
Museum: Building at South Kensington, 895; Exhibits, The Cleaning and Restoration of, Second Report, Dr. A. Scott, 314; Objects, The Circulation of, in the Provinces, 127
Museums, Prof. T. D. A. Cockerell, 184
Music: as a University Subject, Sir Henry Hadow, 722; Instruction in Colleges and High Schools of the U.S.A., Present Status of, 308
Musical Acoustics based on the Pure Third System, T. Kornerup. Translated by Phyllis A. Petersen, 565
Mycetozoa of Surrey, The Dates of Appearance and Habitats of the, P. J. Alexander, 553
Mysore, Meteorology in, N. V. Iyengar, 303

Naga Tribe of Assam, Monoliths of the, J. H. Hutton, 823
Narrow Bands and Wide Bands in the Absorption Spectra of Bodies in Solution and in the State of Vapour, The Production of, V. Henri, 691
Nasal Polypus, A Causal Organism of, Prof. J. H. Ashworth, 719
National: Acclimatisation Society of France, award of the large silver medal to Prof. A. Henry, 680; Health and Medical Research, 421; Museum of Wales, Report of the, for 1921–22, 440; Research Council of America, The, 31; Union of Scientific Workers: Annual Report of the, 157; Dame Helen Gwynne-Vaughan elected president of the, 92
Native Question, Certain Aspects of the, Senator A. W. Roberts, 163
Natural: Coloration, Researches on, effected at the Pic du Midi according to the experiments of J. Bourget, C. Dauzère, 103; Resistance and the Study of Normal Defence Mechanisms, Prof. J. C. G. Ledingham, 85
Naturalist's Calendar, A, kept at Swaffham Bulbeck, Cambridgeshire, L. Blomefield. Second edition, edited by Sir Francis Darwin, 112
Nature: Knowledge and Pastime, Sir Herbert Maxwell, 800; Notes, Critical and Constructive, E. McLennan, 508; Study and Phenology, J. E. Clark and I. D. Margary, 49; The Pageant of, British Wild Life and its Wonders, edited by Dr. P. Chalmers Mitchell. Parts 1, 2, 3, 596
Nebulæ: Gravitation and Light-Pressure in, Prof. F. A. Lindemann, 881; Photographic Studies of, J. C. Duncan, 857; Problems of the, Rev. H. Macpherson, 441; 850 New, Dr. H. Shapley, 717; Hypothesis, The, and Modern Cosmogony: being the Halley Lecture delivered on May 23, 1922, Dr. J. H. Jeans, 662

Nederlandsch Oost-Indië, De Zeeën van, 9
Négatif, Le, en photographie, A. Seyewetz. Deux. édition, 531
Neolithic: Age, A New Industrial Material of the, L. Franchet, 243; Painted Pottery of South-eastern Europe, The, V. G. Childe, 726
Neon Radiations, Study of some, with the View of their Applications to Metrology, A. Pérard, 310
Nerves of the Fingers, Prof. J. S. B. Stopford, 718
Nervous System, The Origin and Development of the, from a Physiological Viewpoint, Prof. C. M. Child, 216
Neurotropic ultravirus, Filtration of, through Collodion Membranes, C. Levaditi and S. Nicolau, 452
New: Brunswick Oil-shale and Gypsum Deposits, 374; South Wales: Geological Survey of, Records of the, 613; Linnean Society of, election of officers and council, Prof. J. P. Hill and Prof. J. T. Wilson elected honorary members of the, 716; No Volcanoes now in, C. A. Sussmilch, 904; Oil Exploration in, L. J. Jones, 303; Royal Society of, election of officers and council, 891; The Freshwater Entomostraca of, Pt. II., Copepoda, Marguerite Henry, 135; Year Honours, 24; Zealand: Geology of, P. G. Morgan, 160; Sand, Hafnium and, Dr. A. Scott, 598; The Vegetation of, Dr. L. Cockayne, 457
Nickel, The Magnetism of, H. Pécheux, 691
Night Sky, Spectrum of the, Further Observations on the, Lord Rayleigh, 418
Nightingale in Uganda, Dr. G. D. Hale Carpenter, 636
Nitrogen: and Hydrogen, The Ionising Potentials of, Dr. H. D. Smyth, 810; Fertilisers for the Sugar Cane, J. Kuyper, 198; Fixation of: by Plants, E. Whitley, 187; by the Wheat Plant, Lipman and Taylor, 95; industry in France, position of the, 543; Peroxide and Camphor, Two Definite Combinations of, P. Pascal and M. Garnier, 347
Nocturnal Sky, Spectrum of the, J. Dufay, 762
Nomenclature, The Rule of Priority in, F. Chapman, 148; Dr. F. A. Bather, 182
Non-ferrous: Alloys, The Analysis of, F. Ibbotson and L. Aitchison. Second edition, 459; Metals Research Association, Bulletin of the, 267
North: Carolina, Fruit-growing in, H. J. Cox and W. N. Hutt, 858; of England Institution of Mining and Mechanical Engineers, the Greenwell medal of the, awarded to Prof. R. V. Wheeler, 240
Northmen in England, The, R. Lennard, 616
Norway and Iceland: an Interesting Contrast, 514
Notothixox incanus (Oliv.) var. *subaureus*, The Parasitism of, J. McLuckie, 136
Nova Aquilæ 1918.4, Light and Colour Variations of, H. Shapley, 555
Novaya Zemlya Island, a Wireless Station to be erected on, 751
Novocaine and Curarisation, H. Laugier and R. Legendre, 554
Number Form, A New Type of, Prof. T. H. Pear, 654
Numbers, the Theory of, History of, Prof. L. E. Dickson, Vol. II., 11
Nutrition de la plante: utilisation des substances ternaires, Prof. M. Molliard, 770

Observer's Handbook, The, 1921 edition, 107
Occult Phenomena and After-images, Dr. F. W. Edridge-Green, 16
Occultism and Modern Science, Prof. T. Osterreich. Translated, 840
Oceanographical Research, Recent, Prof. G. Matthai, 413
Oceanography of the Southern Ocean, Comdr. F. A. Worsley, 302
Odorous Strength, Factors of, T. H. Durrans; F. H. Perrycoste, 359
Oil: engines, tests on, appointment of a committee on, 59; Exploration in N.S.W., L. J. Jones, 303; Fields and the Gravity Balance, 617; in Laccolithic Domes, A. J. Collier and S. H. Cathcart, 342; in Russia, T. G. Madgwick, 61; Palm under Cultivation, The, G. G. Auchinleck, 894; -Well: A French, P. Glangeaud, 684; History of an, A. E. Chambers, 754
Oils and Fats, Technology of, 595
Oklahoma City, prohibition of books, etc., teaching the theory of the evolution of the human race, 406
Oldebroek Explosion of October 28, 1922, the, 32
Oldhamia Rocks of Bray Head,—A Problematic Structure in the, L. B. Smyth, 831
Olivine-bearing Quartz-monzonite from Kiandra, N.S.W., An, W. R. Browne and W. A. Greig, 311
Opalescence, Critical, Application of Photography to the Study of, A. Andant, 347
Optical: Glass, The Refractive Index Changes in, occasioned by Chilling and Tempering, F. Twyman and F. Simeon, 830; Instruments, The Resolving Power and Definition of, A. Mallock, 382; Law, Generalised, 583; Methods in Control and Research Laboratories, Dr. J. N. Goldsmith, Dr. S. J. Lewis, and F. Twyman. Vol. I. Second edition, 566; Society, election of officers and council of the, 337
d'Optique, Essai, sur la gradation de la lumière, P. Bouguer, 320
Ordnance Survey: the Second Geodetic Levelling of England and Wales, 1912–1921, 7
Ore-dressing: A Text-book of, Prof. S. J. Truscott, 696; Modern Processes of, 696
Organ-pipe Diatom, Distribution of the (*Bacillaria paradoxa*), J. W. Williams, 116
Organisms, Contiguity of, Effects of the, Prof. R. Pearl and S. L. Parker, 302
Orionis, θ_2, Variations of the Spectrum of the Star, F. Henroteau, 727, 892
Orthopterous Insect Wing in a Selenite Crystal, Dr. R. J. Tillyard, 374
Osage Oilfield, Wyoming, A. J. Collier, 548
Oscillator, Short Wave, at very low Pressures, Characteristics of a, L. L. Nettleton, 207
Osmotic Effects, The Origin of. IV., Prof. H. E. Armstrong, 689
Osteodystrophic Factors, Some, and their Action according to the Species of Animal, G. Mouriquand and P. Michel, 904
Outdoor Boy, The, edited by E. Wood, 321
Overvoltage, The Measurement of, Dr. S. Glasstone, 775
Overzicht van de theorie en de toepassingen van gassen, waarin de onderlinge botsingen der moleculen kunnen verwaarloosd worden, Dr. J. ter Heerdt, 736
Oxford: Early Science in, Part 2: Mathematics, R. T. Gunther, 75; University: Press, Catalogue of the, 127; Dr. R. A. Peters elected Whiteley professor of Biochemistry, 204; Sir Archibald E. Garrod appointed deputy to Dr. R. A. Peters; the Weldon memorial prize awarded to Dr. J. Schmidt, 240; proposal to establish a new final school in science and philosophy rejected; reports on Forestry and Rural Economy, 273; the Osler Memorial Fund; M. E. Shaw elected Radcliffe travelling fellow; Dr. A. D. Gardner awarded the Radcliffe prize; the Matteucci gold medal handed to Mrs. Sollas as a posthumous honour for the late H. G. Moseley, 485; Sir Michael Sadler elected Master of University College, 621; an annual scholarship in chemistry under the will of Charles Day Dowling Gibbs; establishment of a prize by Mrs. Emily Poulton, 724; annual report of the Savilian professor of astronomy; proposed conferment of degrees on Sir Ernest Rutherford and Prof. L. Lapicque, 828; and Cambridge, Universities of, Bill read a second time, 901
Oxidation: of 1.3.4-Dimethylcyclohexanone and the Synthesis of Cyclopentane Diketones, M. Godchot, 692; of the Metals of the Alkaline Earths, The Heat of, A. Guntz and Benoit, 243
Oxidations and Reductions in the Animal Body, Dr. H. D. Dakin. Second edition, 390
Oxide of Δ_3-Methylcyclohexene and the Dimethylcyclohexanols, M. Godchot and P. Bedos, 103
Oxides, The Action of, and the Oxyacids of Nitrogen on Aromatic Urethanes and Ureas at Low Concentrations of the Reacting Substances, Prof. H. Ryan and others 67
Oxyacetylene Blow-pipe in Spectrum Analysis, Use of the, A. de Gramont, 691

Oxygen in Artificial Respiration, A Mask designed for administering, R. Legendre and M. Nicloux, 275
Oysters and other Lamellibranchs, The Cause of Chambering in, Edith Worsnop and Dr. J. H. Orton, 14

Paints, Industrial, and the Health of the Worker, 685
Palæobotany and the Gondwana Continent, 235
Palæontographical Society, election of officers and council of the, 509
Palæontology and Archaic Fishes, Prof. J. Graham Kerr, 113
Palestine, The Handbook of. Edited by H. C. Luke and E. Keith-Roach, 460
Palolo Worm, The, Dr. G. Corney, 198
Pamir Earthquake of February 18, 1911, The, L. Hawkes, 682
Pan-Pacific Science Congress in Australia, forthcoming, 408
Papua, Native Administration in, J. E. P. Murray, 726
Paraceratherium bugtiense, Skull and Dentition of, C. F. Cooper, 653
Paradromic Rings, Dr. G. T. Bennett, 882
Parallaxes, Photographic Determination of, with the 100-inch Reflector (Mount Wilson), A. van Maanen, 555
Paraquinone, The Ultra-violet Absorption Spectrum of, F. W. Klingstedt, 867
Parasitic Protozoa in Animals and Plants, Dr. C. M. Wenyon, 866
Paré, Ambroise, Life and Times of (1510–1590): with a New Translation of his Policy and an Account of his Journeys in Divers Places, Dr. F. R. Packard, 281
Paris: Academy of Sciences, Bonaparte and Loutreuil Funds, 167; prize awards for 1922, 65; University, gifts to, by Madame E. Nathan, 34
Parsonite, A New Radioactive Mineral, A. Schoep, 207
Pascal, Blaise, The Tricentenary of the Birth of, 407; Prof. H. Wildon Carr, 814.
Pasteur: Centenary: celebrated by the Royal Irish Academy, 371; celebrations: at Lahore, 24; at Paris and Strasbourg, 679; at Paris, 749; Lecture, Prof. J. Loeb, 197; The Work and Ideals of, Dr. P. Vallery-Radot, 204; Institute, The, 693
Pasteurisation of Milk for Cheddar Cheese-making, The Bacteriological Aspect of, J. K. Murray, 311
Pea, Sweet, Linkage in, Prof. R. C. Punnett, 683
Peary Land, Dr. L. Koch, 512
Peat in the United States, E. K. Soper and C. C. Osborn, 582
Pelagic Deposits, Sizes of Particles in certain, Miss A. V. Douglas, 794
Pencil Pigments in Writing, C. Ainsworth Mitchell, 61
Penrose's Annual: The Process Year Book. Edited by W. Gamble. Vol. 25, 11
Pentacrinidæ, Recent, A. H. Clark, 340
Periodical Literature, An Index to, 214
Periodicals, The Subject Index to, K: Science and Technology; 1920, A: Theology and Philosophy (including Folk-lore), 214
Peromyseus, Studies of Sub-specific Hybrids in, F. B. Sumner, 555
Perry Auto-time Morse System: an Aid to the Rapid Acquirement of Speed in the Transmission and Reception of the Morse Code, F. W. Perry, 628
Perseid Meteors in July 1592, W. F. Denning, 848
Perthshire Naturalist, A: Charles Macintosh of Inver, H. Coates. With a chapter on Scottish Folk-music by H. Wiseman, 800
Peru, North-west Part of, Geology of the Tertiary and Quaternary Periods in the, Dr. T. O. Bosworth and others, 527
Peruvian Desert, A, Dr. J. W. Evans, 527
Pests of the Garden and Orchard, R. Palmer and W. P. Westall, 530
Petrograd: Academy of Science, Geological Museum of the, Opening of New Premises of the, 891; Principal Botanical Garden at, Dr. J. Palibin appointed assistant to the museum director in the, 644
Petroleum: A Trial Boring for, at Crouelle, near Clermont-Ferrand (Puy-de-Dôme), 520; Egyptian, W. A. Guthrie, 894; Origins of, Jun-ichi-Takahashi, 374
Petrology of the Arnage District in Aberdeenshire, The, H. H. Read, 485
Petty, Sir William, The Tercentenary of, 676
Pflanzenanatomie, Handbuch der, 1 Abtg., 1 Teil: Cytologie. Band 1: Zelle und Cytoplasma, H. Lundegårdh, 72; 2 Abtg., 1 Teil. Band 6, von Prof. R. Lieske, 355
Phantasms of the Living, Dr. T. W. Mitchell, 211
Phase Rule, The, and its Applications, Prof. A. Findlay. Fifth edition, 631
Phenological Observations on Plants, Dr. E. Vanderlinden, 129
Phenology, Nature Study and, J. E. Clark and I. D. Margary, 49
Philippine Earthquakes, 61
Philippines, Weather in the, Rev. J. Algué, 129
Philosophy for Men of Science, 872
Phosphates as Fertilisers, Discovery of the Use of, Sir John Russell and A. Henderson Smith, 116
Phosphatic Manures, Researches on the Assimilability of, A. Demolon and P. Boischot, 488
Phosphorescence caused by Active Nitrogen, Prof. E. P. Lewis, 599; W. Jevons, 705
Photo-elastic Research, Prof. E. G. Coker, 341
Photographic: Plate, Development Centres in the, W. Clark, 684; Plates containing Mercury Salts, The Sensibility of, G. Athanasiu, 795; Sensitisers and Desensitisers, Prof. R. Namias, 29; Theory, Recent Advances in, Dr. C. E. K. Mees, 399
Photometric Terms and Units, Adoption of the Provisional Definitions of, 857
Photometry, E. C. Crittenden, 512
Photo-micrographs, An Improved Apparatus for the Production of, M. T. Denne, 486
Photosynthesis of Plant Products, The, Prof. I. M. Heilbron, 502
Physical: Apparatus, Exhibition of, 63; Chemical and, Tables, 493; Literature on the Continent, Dr. R. W. Lawson, 635
Physico-chemical Themes, Some, Prof. A. W. Stewart, 733
Physics: Allurements in, Prof. G. W. Stewart, 482; and Psychics, Surg. Rear-Admiral C. M. Beadnell, 139; Applications of, to the Ceramic Industries, Dr. J. W. Mellor, 757; Applied, A Dictionary of. Edited by Sir Richard Glazebrook. In 5 Volumes, Vol. 3, 558; in Industry at the Wembley Laboratories, 344; Molecular, Dr. J. A. Crowther. Third edition, 279; Radiography and, Dr. G. W. C. Kaye, 364; The Institute of, associate membership of, 544
Physioklimatologie der Festländer, Grundzüge einer, Dr. W. R. Eckardt, 392
Physiological Congress, International, to be held in Edinburgh, 613
Physiology in Medicine, Prof. E. H. Starling, 314
Physique: mathématique, Cours de, de la Faculté des Sciences, Prof. J. Boussinesq. Compléments au tome 3, 356; Société Française de, Fiftieth Anniversary of the, 856
Phytophthora, Oospore Formation in, S. F. Ashby, 61
Phytophthoras, Studies on, Miss de Bruyn; Miss M. P. Löhnis, 305
Picryl Sulphide, Researches on, A. Roche and V. Thomas, 451
Pidgeon, Daniel, Fund, The proceeds of the, awarded to H. Williams, 477
Pigmentary Effector System, The, III., Dr. L. T. Hogben and F. R. Winton, 450
Pilou Feast in New Caledonia, The, M. Leenhardt, 61
Pinacolic and Semi-pinacolic Transpositions, Tiffeneau and Mlle. J. Lévy, 275
Pinacones, Preparation of Various, by the Action of Alkyl Magnesium Compounds on some α-Hydroxy-Methyl Ketones, R. Locquin and S. Wouseng, 452
Pitch, the Properties of, used in Working Optical Glass, F. W. Preston, 346
Plaice Fishing Ground, Impoverishment of a, Dr. C. G. J. Peterson, 414
Planck Constant *h*, The Value of the, R. T. Birge, 811
Planet, Lost, Recovered, 159
Planetary Radiation, W. W. Coblentz, 510

Planets: Giant, Present Condition of the, Dr. H. Jeffreys, 615; Observation of the, and Relativity, J. Trousset, 554
Plankton Investigations in the Irish Sea, Some Results of, Sir William Herdman, 448
Plant and Animal Designs in the Mural Decorations of an Uriya Village, Dr. N. Annandale, 832; Cuticle, The Strength of the, Prof. V. H. Blackman and others, 373; Distribution, Soil Acidity and, C. Olsen, 791; Ecology, Dr. E. Frey and others, 827; Extracts, Effect of, on Blood Sugar, Prof. J. B. Collip, 571; Gall, Structure and Origin of the, Prof. M. T. Cook, 483; -life, The Earlier Records of, Prof. A. C. Seward, 485; Physiology in Agriculture, The Rôle of, Mrs. Howard, 413; Products, The Photosynthesis of, Prof. I. M. Heilbron, 502; Protoplasm, Observations on the Necrobiosis of, with the Aid of a New Reagent, P. Becquerel, 451
Plants: Comparative Embryology of, Prof. F. O. Bower, 270; Diseases of, in England in 1920–21, Dr. E. J. Butler, 416; Modification of, submitted to Culture under Glass, Mlle. L. Blum, 655; New, under Cultivation, Dr. Stapf, 480; The Respiratory System of, M. Popoff, 451; Virus Diseases of, Dr. E. J. Butler, 551
Plasmodia, etc., The Imitation of, A. L. Herrera, 655
Plasmopara, Infection and Cytological Studies of, M. Nishimura, 547
Plaster of Paris, Baking of, and its Preservation in Moist Air, P. Jolibois and P. Lefebvre, 831
Pleasure Principle, Beyond the, Dr. S. Freud. Translated by C. J. M. Hubback, 316
Pleiades, Observations of the, with the Heterochrome Photometer of the Paris Observatory, C. Nordmann and C. Le Morvan, 655
Pocket Magnifier, A New Type of, Cooke, Troughton and Simms, Ltd., 509
Poetry and Science, No Opposition between, O. C. de C. Ellis, 890
Poincaré Electron in Weyl's Geometry, The Interior and Exterior Space-time forms of the, J. Marshall, 795
Poisoning by Illuminating Gas, 293
Polariscope and the Polarising Microscope, The Early History of the, Prof. F. J. Cheshire, 171
Polarity, G. Sainsbury, 78
Pole, North, Abandonment of Capt. Amundsen's Projected Flight across the, 890
Polish: Chemists and Physicists, The First Congress of, 579; Wheat Cross, Peculiar, F. L. Engledow, 719
Polyphenols: An Application of the Antioxygen Power of the, A. Gillet and F. Giot, 867; A Verification of the Antioxygen Power of the, A. Gillet, 795
Polysiphonia, The Genus, Lily Batten, 67
Polythrincium Trifolii, The Life History of, J. S. B. Elliott and O. P. Stansfield, 553
Pomology, Journal of, and Horticultural Science, 340
Population in the Cambridge Region in Early Times, Distribution of, C. Fox, 67
Porto: Rico, Physiography of, A. K. Lobeck, 443; Santo in Pleistocene Times, Prof. T. D. A. Cockerell, 464
Positions at Sea, A Radio-acoustic Method of locating, Dr. A. B. Wood and Capt. H. E. Brown, 887
Post-Columbian Words used by the Indians of S. America, Deductions suggested by the Geographical Distribution of some, Baron Erland Nordenskiold, 665
Pot Furnaces, Organising for Production from, W. W. Warren, 420
Potassium Permanganate, The Photochemistry of, Pts. I. and II., Dr. E. K. Rideal and R. G. W. Norrish, 168
Potato: Foliage, The Cause of Rolling in, P. A. Murphy, 487; Regeneration of the, by Grafting, L. Daniel, 520; The Mildew of, Action of Insoluble Oxides on, M. and Mme. G. Villedieu, 383; Tuber, The Causal Anatomy of the, Prof. J. H. Priestley, 553
Poultry Keeping on the Farm, E. Brown, 804
Powders, The Properties of, J. H. Shaxby and J. C. Evans, E. E. Walker, 690
Prague: Academy of Sciences of, *Bulletin International* of the, 822; Charles' University, The degree of Doctor Rerum Naturalium conferred on J. G. F. Druce, 102
Preservation and Restoration, 313
Primitive Plants, The Relation of Size to the Elaboration of Form and Structure of the Vascular Tracts in, Prof. F. O. Bower, 419
Primulas of Central Asia, F. K. Ward, 443
Princeton University, conferment of the honorary degree of doctor of laws upon Sir Frederic Kenyon, 301
"Principia," Definitions and Laws of Motion in the, Prof. W. Peddie, Prof. F. E. Hackett, 395
Printing Works, Lighting of, L. Gaster, 612
Procellose, A New Sugar, G. Bertrand and Mlle. S. Benoist, 903
Productivity, Genetics of, Sax and Gowen, 582
Protein Molecule Existence of an Unidentified Sulphur Grouping in the, L. J. Harris, 274
Protozoa of the Soil, The, D. W. Cutler, 653
Pseudo-Butyl-Diphenylcarbinol Series, A Molecular Transposition in the, P. Ramart, 452
Psilotaceæ, Modern, and Archaic Terrestrial Plants, Prof. B. Sahni, 84
Psychical Research: Proceedings of the Society for. Vol. 33, Part 86, 211; The Goligher Circle, May to August 1921, Dr. E. E. Fournier d'Albe, 139
Psychics, Physics and, Surg. Rear-Admiral C. M. Beadnell, 139
Psychoanalysis, Fundamental Conceptions of, Dr. A. A. Brill, 316; Studies in, An Account of Twenty-seven Concrete Cases preceded by a Theoretical Exposition, C. Baudouin. Translated by E. and C. Paul, 316
Psycho-biology, E. S. Russell, 419
Psychologie, vergleichenden, Handbuch der, Herausgegeben von G. Kafka. Bands 1, 2, 3, 354
Psychology: and Criminal Responsibility, Dr. W. Brown, 581; Comparative, 354; Group, and the Analysis of the Ego, Dr. S. Freud. Translated by J. Strachey, 321; Medical, and Psychical Research, Dr. T. W. Mitchell, 316; Normal and Abnormal, 316; Scientific, The Elements of, Prof. K. Dunlap, 392; The Position of, Sir Charles Sherrington, 439
Psychotherapy, 803
Public Analysts, Society of, election of officers and council of the, 266
Pulfrich's Experiment demonstrating Time-lag in Vision, F. Ll. Hopwood, 691
Puzzle Paper Band, A, Prof. C. V. Boys, 774; Annie D. Betts, 882
Pylaiella litoralis, The Life History and Cytology of, Miss Margery Knight, 420
Pyramids of Meroe, The, and the Candaces of Ethiopia, Prof. G. A. Reisner, 410

Quaker Aspects of Truth, Dr. E. V. Brown, 145
Quantum Theory: The, Prof. F. Reiche. Translated by Dr. H. S. Hatfield and H. L. Brose, 279; The Development of the, Prof. H. S. Allen, 279; The Wave Theory and the, Prof. C. G. Darwin, 771
Quartz (Silver Sand), The Effect of Long Grinding on, R. C. Ray, 169
Quest film, the, 58
Química Experimental, Prof. R. Galarza. I.: Mineral, 285

Race Study, Mental and Physical Characters in, Prof. H. J. Fleure, 268
Radiation: Primary and Secondary, Prof. H. A. Lorentz, 791; Problem, Present Position of the, Dr. J. H. Jeans, 761; Theory, 791
Radio: Amateur's Hand Book, The, A. F. Collins, 427; -Communication, Science and, Sir Richard Glazebrook, 709; in Relation to Weather Observations, E. B. Calvert, 720; Phone Receiving: a Practical Book for Everybody. Edited by Prof. E. Hausmann, 628; Receiving: Outfit, and Radio Receiving Equipment with Crystal Detector, Home-made, 614; Sets, U.S. circulars on, 781; -telephonic Communication between Great Britain and the United States, 93; Telephony, Long-Distance, 123; Transmittance of the Telegraph Alphabet, Genl. Squier, 783; Year Book, The, 1923, 460
Radioactive Disintegration, S. Rosseland, 357

Radiography: and Physics, Dr. G. W. C. Kaye, 364; applied to the Study of the Lesions of Prehistoric Human Bones, M. Baudouin, 488
Radiophones, 628
Radiotéléphonie, La, C. Toché, 460
Radium: -D and Radium-E, The γ-Radiation of, Mlle. I. Curie and G. Fournier, 762; Emanation: the Products of, Bactericidal Properties of, J. A. Marshall, 36; The Quantitative Measurement of, by the α-Radiation, A. Lepape, 903; Industry, The Present Situation in the, H. E. Bishop, 614
Raffles Museum and Library, Report for 1921, 26
Railway Manual, A, 564
Rainfall: Annual, The Fluctuations of, in the British Isles considered Cartographically, M. de Carle S. Salter and J. Glasspoole, 727; British, 1921, 181; Data, Paradoxical, Prof. A. M'Adie, 362; R. A. Fisher, 465; in 1922, 235
Rana temporaria, An Overlooked Feature in Four-legged Tadpoles of, O. H. Latter, 151
Ranger Oilfield, Texas, F. Reeves, 481
Ranges and Cooking Appliances, Tests on, A. H. Barker, 415
Rat Repression, The Rodier System of, A. E. Moore, 671
Rayonnement et gravitation, F. Michaud, 217
Ray Society, election of officers and council of the, 477
α-Ray Tracks, The Natural Curvature of, P. M. S. Blackett, 519
Rea's "British Basidiomycetæ," Prof. A. H. R. Buller, 213
Reconstruction, Methods and Technique of, J. R. Norman, 103
Recording Time with an electrically maintained Pendulum, H. Chrétien, 554
Red Sea-water due to a Dinoflagellate, K. Hirasaka, 753
Reflexes, Conditioned, The Irradiation of, G. V. Anrep, 274
Refraction, The Form of the Wave-surface of, A. Whitwell, 623
Reinforced Concrete simply explained, Dr. Faber, 251
Relativité d'Einstein, La Théorie de la, et ses bases physiques: exposé élémentaire, Dr. Max Born. Traduit par Dr. F.-A. Finkelstein et J.-G. Verdier, 697
Relativity: and Scientific Method, Dr. Dorothy Wrinch, 100; Chapter XVI. Modern Electrical Theory: Supplementary Chapters, Dr. N. R. Campbell, 697; General, The Theory of, and Gravitation: based on a Course of Lectures delivered at the Conference on Recent Advances in Physics held at the University of Toronto in January 1921, Dr. L. Silberstein, 697; New Works on, 697; The General Principle of, in its Philosophical and Historical Aspect, Prof. H. Wildon Carr. Second edition, 697; The Mathematical Theory of, Prof. A. Kopff. Translated by Prof. H. Levy, 697; Prof. A. S. Eddington, 697; The Meaning of, Four Lectures delivered at Princeton University, May 1921, Prof. A. Einstein. Translated by Prof. E. P. Adams, 697; The Mechanism behind, Prof. W. Peddie, 795; The Principle of, with Applications to Physical Science, Prof. A. N. Whitehead, 697; the Theory of, Vector Analysis and, Prof. F. D. Murnaghan, 697
Religion: and Biology, E. E. Unwin, 531; and Evolution, Rev. Canon E. W. Barnes, 526; Classification in, The Problem of, W. A. Brown, 134; Psychology of, An Introduction to the, R. H. Thouless, 805; Science and, Dr. J. S. Haldane and others, 729
Remembering and Forgetting, Prof. T. H. Pear, 316
Reptilian Remains from the Karroo Beds of East Africa, S. H. Haughton, 242
"Research: Fountain Pen," The, A. Munro, 682; in India, The Organisation of, 797; Laboratories, Value of, Sir Richard Glazebrook, 714
Resonance: Multiple, P. Rothwell, 254; Radiation: Destruction of the Polarisation of, by Weak Magnetic Fields, Prof. R. W. Wood and A. Ellett, 255; Polarisation of, Influence of Magnetic Fields on the, Prof. R. W. Wood and A. Ellett, 690
Restoration, Preservation and, 313
Retzius, Anders, medal in gold, the, conferred upon Sir Aurel Stein, 579

REVIEWS AND OUR BOOKSHELF

Agriculture, Forestry, and Horticulture:

Brown (E.), Poultry Keeping on the Farm, 804
Farm Animals, Cyclopedia of. Edited by Dr. L. H. Bailey, 140
Farm Crops: Cyclopedia of, A Popular Survey of Crops and Crop-making Methods in the United States and Canada. Edited by Dr. L. H. Bailey, 140
Foster (W. A.) and D. G. Carter, Farm Buildings, 391
Halnan (E. T.), Animal Nutrition: Foods and Feeding, 804
McKay (Dr. G. L.) and Prof. C. Larsen, Principles and Practice of Butter-Making. Third edition, 77
Orwin (C. S.), Farm Costing and Accounts, 804
Roebuck (A.), Insect Pests and Fungous Diseases of Farm Crops, 804
Rohde (Eleanour Sinclair), The Old English Herbals, 143
Willis (Dr. J. C.), Agriculture in the Tropics: an Elementary Treatise. Third edition, 876

Anthropology and Archæology:

Åberg (Dr. N.), Die Franken und Westgoten in der Völkerwanderungszeit, 454; La Civilisation énéolithique dans la Péninsule Ibérique, 563
Bender (Prof. H. H.), The Home of the Indo-Europeans, 111
British Museum. Guide to the Maudslay Collection of Maya Sculptures (Casts and Originals) from Central America, 631
Fleming (R. M.), Stories from the Early World, 284
Fleure (Prof. H. J.), The Races of England and Wales: a Survey of Recent Research, 737
Frazer (Sir James George), The Golden Bough: A Study in Magic and Religion. Abridged edition, 658
MacMichael (H. A.), A History of the Arabs in the Sudan: and some Account of the People who preceded them and of the Tribes inhabiting Dárfúr. 2 vols., 176
McGovern (Janet B. Montgomery), Among the Head-hunters of Formosa, 284
Melanesia, Depopulation of, Essays on the. Edited by Dr. W. H. R. Rivers, 145
Mills (J. P.), The Lhota Nagas, with an Introduction and Supplementary Notes by J. H. Hutton, 282
Nordenskiold (Baron E.), Comparative Ethnographical Studies, 5; Deductions suggested by the Geographical Distribution of some Post-Columbian Words used by the Indians of S. America, 665
Peake (H.), The Bronze Age and the Celtic World, 454
Quennell (Marjorie and C. H. B.), Everyday Life in the New Stone, Bronze, and Early Iron Ages, 700
Smith (S. P.), Hawaiki: the Original Home of the Maori. With a Sketch of Polynesian History. Fourth edition, 736
Werth (E.), Der fossile Mensch. Zweiter Teil, 701
White (W. G.), The Sea Gypsies of Malaya: an Account of the Nomadic Mawken People of the Mergui Archipelago, 566

Biology:

Andrews (E. A.), Factors affecting the Control of the Tea Mosquito Bug (Helopeltis theivora *Waterh.*), 875
Anthony (Prof. R.), Le Déterminisme et l'adaptation morphologiques en biologie animale. Première partie, 664
Babington (C. C.). Tenth edition. Edited by A. J. Wilmott. Manual of British Botany: containing the Flowering Plants and Ferns arranged according to the Natural Orders, 251
Baker (Dr. E. A.), The Highlands with Rope and Rucksack, 800

Overton (G. L.), Clocks and Watches, 77
Penrose's Annual: The Process Year Book, edited by W. Gamble. Vol. 25, 11
Rau (M. C. S. Anantapadmanabha), The Planning and Fitting up of School Laboratories, 284
Rubigny (F.), Manuel de filature, 356

Reviews and Reviewers, Sir Richard Gregory, 94
Rhexoxylon, Bancroft: a Triassic Genus of Plants exhibiting a Liane-type of Vascular Organisation, J. Walton, 450
Rhombic Pyroxene, Genesis of, in Thermal Metamorphism; Mineral Associations and the Phase Rule, C. E. Tilley, 486
Riemann Spaces conformal to Euclidean Space, H. W. Brinkmann, 554
Rockefeller Foundation's Gift of the Institute of Anatomy to University College, London, 755
Rocks of Adrar des Iforass and Ahaggar, The, M. E. Denaeyer, 692
Rodier System of Rat Repression, The, A. E. Moore, 671
Roman: Fortified House near Cardiff, A, R. E. M. Wheeler, 647; Walls in Northern Britain, The, G. Macdonald; R. G. Collingwood, 616
Röntgen, Les Forces de Valence et les Spectres de, Prof. Kossel, 510
Rosewood, The Resinous Exudation of, M. B. Welch, 311
Ross Clinique for Tropical Diseases, A Proposed, 889
Rotation of the Shaft of a Motor, The Rapid and Precise Measurement of the Frequency of, by the Stroboscopic Method, A. Guillet, 831
Rotatory Power, Natural and Magnetic, R. Lucas, 171
Rothamsted: and Agricultural Science, Sir John Russell, 466; Experimental: Fields, invitation to farmers and others to visit, 370; Station: Annual Visitation, 863; Dr. B. A. Keen appointed assistant director of the, 890
Rowett Research Institute for Animal Nutrition, gifts to the, 158, 266
Royal: Academy, The, 1923, 642; Agricultural Society, Work of the Research Committee of the, 856; Astronomical Society: award of the gold medal of the, to Prof. A. A. Michelson, 125; presented, 240; election of officers and council of the, 232; College of Surgeons of England, award of the Jacksonian prize to H. S. Forsdike; Sir Arthur Keith elected Vicary lecturer, 544; Egyptian Tombs, The Plundering of, Prof. T. E. Peet; Dr. A. M. Blackman, 234; Engineers: Institution of, grant of a Royal Charter of Incorporation to the, 371; The Work of the, in the European War, 1914–19, Military Mining, 663; Work in the Field under the Engineer-in-Chief, B.E.F.; Geological Work on the Western Front; Work in the Field in other Theatres of War, Egypt

and Palestine—Water Supply, 873; Geographical Society, awards of the, 544; Horticultural Society, Journal of the, Part I. Vol. 18, 821; Institution: election of officers, 646; Sir William Bragg elected Fullerian professor of chemistry, director of the Laboratory, and of the Davy Faraday Research Laboratory, 783; Meteorological Society, election of officers and council of the, 266; Observatory, Greenwich, Annual Visitation, 789; Scottish Society of Arts, award of prizes by the, 92; Society: Conversazione, the, 721; gold medals, the, struck in brass, 819; Munificent Gift from Sir Alfred Yarrow, 261; recommendations for new fellows of the, 298; and Heidelberg University, bequests to the, by Dr. L. Mond, 714; of Edinburgh, Prof. R. A. Sampson appointed General Secretary of the, 125
Rubber, Vulcanisation of, V. V. Byzov, 648
Ruby, The Cathode Phosphorescence of the, J. Rossignol, 831
Rümkers, Carl, Hamburger Sternverzeichnis 1845.0, herausgegeben von Dr. R. Schorr, 564
Russian Proper Names, Transcription of, Prof. B. Brauner, 290
Rusts: in South Africa, Dr. M. Pole-Evans, 373; upon Cereals, The Spread of, Prof. K. C. Mehta, 582

Saccharometer for Brewing, A Recording, Negretti and Zambra, 375
Sahara, Surveys of the, 410
St.: Andrews University: appointments in, 168; honorary degrees to be conferred on Sir William Henry Hadow, H. W. Richmond, and Sir Robert Robertson, 723; institution of a prize in surgery in honour of Dr. D. McEwan, 792; Austell Granite (Cornwall): A Micrometric Study of the, W. A. Richardson, 134; Rutile, Brookite, and Anatase in the, J. G. C. Leech, 486; Bartholomew's Hospital, The 800th Anniversary of the Foundation of, 777
Sakura-jima, The Eruption of, in 1914 (Prof. Omori), Dr. C. Davison, 516
Salernum: The School of, Regimen Sanitatis Salernitanum. The English Version, by Sir John Harington; History of the School of Salernum, by Dr. F. R. Packard, and a Note on the Pre-history of the Regimen Sanitatis, by Dr. F. H. Garrison, 281
Saltcake, The Effect of, in Corroding Fireclay Materials, Edith M. Firth, F. W. Hodkin, and Prof. W. E. S. Turner, 519
Sand, Crushed, Law governing the Connexion between the Number of Particles and their Diameters in Grinding, C. E. Blyth, Dr. G. Martin, and H. Tongue, 842
Sanderson of Oundle School, Sir John Russell, 731
Sands for Various Industrial Purposes, The Microscopical Investigation of, H. B. Milner, 902
Santa: Cruz, a new meteorological observatory at, 337; *Maria*, a model of the, in the Science Museum, South Kensington, 439
Sarawak, Dr. C. Hose, 369
Sarsen Stones, Discovery of, near Maidstone, 195, 234; C. Carus-Wilson, 292
Saturn's Satellites, The Diameters of, Major P. A. Hepburn, 752
School: and Sex, 657; Geometry, Sequence in, 277; Laboratories, The Planning and Fitting Up of, M. C. S. Anantapadmanabha Rau, 284
Science: *Abstracts*, 267; and Armaments, Dr. L. C. Martin, 82, 429; Dr. J. Weir French, 186; and Art, The Relations of, Prof. B. Pite, 439; and Economics, W. W. Leisenring, 571, 846; Prof. F. Soddy, 669; St. George Lane Fox Pitt, 670; and Government Administration, Lt.-Col. M. O'Gorman, 521; and Industry in Sweden, 851; and Practical Life, Earl Balfour, 439; and Radio-Communication, Sir Richard Glazebrook, 709; and Religion, Dr. J. S. Haldane and others, 729; and Superstition of Primitive Mankind, Dr. B. Malinowski, 658; Aspects of, J. W. N. Sullivan, 529; Education and, in the Civil Service Estimates, 557; Elementary, Nature Study, and Practical Work in Preparatory Schools and the Lower Forms of Secondary Schools, 173; in Schools, Methods of teaching, Miss M. B. Thomas, 100; in Secondary Schools, 70; Industrial, Fact and Phantasy in, C. F. Cross, 585; Labour and, in Industry, 385; Masters' Association, Annual Meeting of the, 99; Museum Collections, Position and Needs of the, 869; Paradoxical, 319; Teachers in Conference, 99; Teaching, 173; The Religion of, Prof. W. H. Wood, 526; The Social Influence of, F. S. Marvin, 209; Ad. K., 361; F. S. Marvin, 362; The Support and Utilisation of, Dr. A. A. Griffith, 92
Sciences naturelles, Les, Dr. G. Matisse, 251
Scientific: and Industrial Research, Report of the Committee of the Privy Council for, 1921–22, 165; and Learned Societies of Great Britain and Ireland, The Year-Book of the, Thirty-ninth annual issue, 389; and Technical: Books, Recent, Suppt. (January 27), iii, Suppt. (February 24), iii, Suppt. (March 31), v, Suppt. (April 28), v, Suppt. (May 26), v, Suppt. (June 23), v; periodicals in Dublin libraries, Catalogue, Dr. R. L. Praeger, 487; Expeditionary Research, 64; Association, the position of the, 819; Instrument Research Association, Report of the, 232; Papers, Notes on the Composition of, Sir T. Clifford Allbutt. Third edition, 490; Periodicals for Czech Students, B. O. Tufnell, 397; Societies in the British Isles, 389; Thought, Prof. C. D. Broad, 872; Worker, The Position of the, W. Graham and others, 132; Worthies, XLII. H. A. Lorentz, Sir Joseph Larmor, 1
Scott, John, medal, awarded to Sir Joseph Thomson, Dr. F. W. Aston, Dr. C. Eijkman, and Dr. A. L. Day, 680
Scott's Last Journey, The Meteorology of, Dr. G. C. Simpson, 758
Scurvy in the Guinea-pig and Young Rabbit by means of a new Food Regime, The Production of, M. Lopez-Lomba and Mme. Randoin, 654
Sea: Gypsies of Malaya, The: an Account of the Nomadic Mawken People of the Mergui Archipelago, W. G. White, 566; -level: Changes in Denmark, Dr. K. Jessen, 787; The Fluctuations of Mean, in Relation to Change of Atmospheric Pressure, E. C. Shankland, 587; Slug, Dorsal Eyes of the, K. Hirasaka, 787; the Exploitation of the, 414; The Invasion of the, on the Coast of Berck and the Teachings of Recent Geology, A. Briquet, 275; Water, The Hydrogen-ion Concentration of, Dr. W. R. G. Atkins, 132
Secondary: Schools: Science in, 70; Liberal Education in, 862; University and, Education, 833
Secret Sects of Syria and the Lebanon: a Consideration of their Origin, Creeds and Religious Ceremonies, and their Connection with and Influence upon Modern Freemasonry, B. H. Springett, 285
Sed Festival of Ancient Egypt, The, P. E. Newberry, 378
Seeds: in Inert Gases, Preservation of, J. Houdas, 795; the Germination of, Effect of Moonlight on, Elizabeth Sidney Semmens, 49
Segregation, Selection and, Prof. A. Willey, 602; Sir G. Archdall Reid, 806
Seismic Waves in a Visco-elastic Earth, H. M. Hosali, 866
Selection and Segregation, Prof. A. Willey, 602; Sir G. Archdall Reid, 806
Sex, School and, 657
Shackleton-Rowett (*Quest*) Expedition, Geological Results of the, G. V. Douglas, 274
"Sheep-Tracks" on Grassy Slopes, H. Ødum, 786
Sheffield University: W. Vickers appointed lecturer in education and master of method, 240; E. G. Allan appointed assistant bacteriologist; H. P. Lewis assistant lecturer in mining geology, 380; opening of the Jonas and Edgar Allen Laboratories of, 750; Anonymous Gift to, 864
Shield Tunnelling, 798
Ship Model Experiment Data, The Presentation of, Telfer, 130
Shipworm, Digestion of Wood by the, Dr. P. Bartsch, 28
Shirley Institute Memoirs, Vol. I., 542
Shock in Medicine, The Similitude of Forms of, their dangerous but avoidable Superposition, F. de Courmelles, 796
Shrunk Human Heads, Sir John Bland-Sutton, 95

Sierra Leone, Petrographic Survey of, Dr. F. Dixey, 410
Sikhs of the Punjab, The, 234
Silent Zone in Explosion Sound-Areas, The, Dr. C. Davison, 117
Silica: in Sedimentary Rocks, Deposition of, H. B. Manfe; T. B. Lawler, 412; in Water, Estimation of, F. Diénert and F. Wandenbulcke, 831; Vitreous, The Hardness of, C. Johns and Prof. C. H. Desch, 15
Silicon, Trebly-ionised, The Series Spectrum of (Si IV), Prof. A. Fowler, 689
Silkworm, Diseases in, Dr. A. P. Jameson, 411
Sillimanite, Natural, as a Glass Refractory, S. English, 830
Silver Sulphate, The Dissociation of, Mlle. G. Marchal, 275
Sioux Tribe, Early History of the, Dr. J. R. Swanton, 480
Sky-types, Forecasting, D. E. Row, 35
Slag mistaken for a Meteorite at Quetta, G. H. Tipper, 704
Sleep Movements and Vegetative Reproduction in Plants, W. T. Saxton; R. H. Dastur, 823
Sleeping Sickness, Cure of, Dr. A. Balfour, 339
Smell: and Specific Gravity, J. H. Kenneth, 151; Taste, and Allied Senses in the Vertebrates, Prof. G. H. Parker, 629
Smokes, Pt. I., R. Whytlaw-Gray, J. B. Speakman, and J. H. P. Campbell; Pt. II., R. Whytlaw-Gray and J. B. Speakman, 169
Snail, Pond, The Name of the, F. A. B., 150
Soaring Flight and the "Olfactory" Organs of Birds, Lt.-Col. W. E. M'Kechnie, 48
Social Question, The New, Capt. J. W. Petavel, 688
Société Française de Physique, the, 783
Society, The Psychology of, M. Ginsberg, 145
Sociology, Biological Contributions to, Prof. J. A. Thomson, 300
Sodammonium, The Action of, on Aniline and its Homologues, M. Picon, 35
Sodium: Hypochlorite, The Catalytic Decomposition of, by Cobalt Peroxide, O. R. Howell, 866; Metaphosphate, The Preparation of, at a Low Temperature, P. Pascal, 795
Soil: Acidity and Plant Distribution, C. Olsen, 791; Bacteria: and Organic Antiseptics, P. H. Gray, 893; The Destruction of Aromatic Antiseptics by, H. G. Thornton, 347; Partial Sterilisation of, Sir John Russell, 347; Reaction, Water Snails, and Liver Flukes, Dr. W. R. G. Atkins and M. V. Lebour, 83; C. L. Walton, 117; -types, Mineral Constitution of, Prof. J. Hendrick and G. Newlands, 786
Soiling System, devotion, by E. D. Simon, of a farm and dairy herd to test, 126
Sol, Study of the Reversible, to get Transition in Non-liqueous Systems, Pts. I. and II., E. W. J. Mardles, 170
Solanaceous Plants, Some Causes of Sterility in, due to Protozoa and Chytridiaceous Parasites, M. S. G. Breeze, 866
Solar: Apex, Position of the, J. S. Paraskevopoulos, 159; Eclipse Investigations, Prof. A. D. Ross, 510; Eclipses, Coming, 60; Prominence Activity, 27; Radiation, Prof. C. G. Abbot and others, 414
Solids and Liquids, Calorific Capacity of, The Principle of a General Method for determining the, C. Moureu, C. Dufraisse, and P. Landrieu, 867
Solution: of Oxygen by Water, Irregularities in the Rate of, H. G. Becker and E. F. Pearson, 487; The Law of, P. Mondain-Monval, 275; Variation of Heats of, with Temperature, P. Mondain-Monval, 554
Sorby, Henry Clifton, The Services of, to Metallurgy, Prof. C. H. Desch, 478
South Africa: Astronomical Society of, 717; Botanical Society of, 680; Citrus Fruit from, Miss Thomson, Putterill and Hobson, 234; medal and grant, award of the, to Dr. I. B. Pole Evans, 162; Post-Cretaceous Climates of, Dr. A. W. Rogers, 162; Recent Volcanic Activity in, Dr. P. A. Wagner, 235; Royal Society of, election of officers, 613: Union of, Fisheries and Marine Biological Survey, Reports for 1920 and 1921, Dr. J. D. F. Gilchrist, 270
South African: Association, The Lourenço Marques Meeting of the, 162: Fisheries, Exploitation of, Prof. J. S. Gardiner, 270; Institution of Engineers, The Central Mining-Rand Mines Premium awarded by the, to W. J. Horne, 439
Southampton, University College, G. Grant appointed Registrar, 586
South-eastern Union of Scientific Societies, Annual Congress of the, 860
Southport, Meteorological Observations at, J. Baxendell, 341
Space: Groups and Crystal Structure, R. W. G. Wyckoff, 444; The Finitistic Theory of, Dr. Petronievics, Dr. N. M. Poppovich, 161
Spahlinger Treatment of Tuberculosis, The, Dr. L. Williams, 453
Spark: -gaps in which the Spark in a Gaseous Dielectric is deflected by a Strong Air Current, J. L. Breton, 383; Spectra of Higher Order, L. and E. Bloch, 520
Specific Gravity Determinations, A Graphical Method of correcting, Dr. A. Hutchinson, 486
Spectra: associated with Carbon, Prof. T. R. Merton and R. C. Johnson, 622; Induction, and Spark Spectra, L. Dunoyer, 588; The Theory of, and Atomic Constitution: Three Essays, Prof. N. Bohr, 523
Spectrometry, Use of the Triode Valve in, L. Bellingham, 534
Spectrum, The Disappearing Gap in the, Prof. O. W. Richardson, 118, 153
Speech: Sounds, Nature and Reproduction of, Sir Richard Paget, 21; The Transmission of, by Light, Prof. A. O. Rankine, 744
Spermatogenesis of the Lepidoptera, H. G. Cannon, 670
Sphere, Free Motion of a, in a Rotating Liquid at Right Angles to the Axis of Rotation, S. F. Grace, 866
Spiders of New Caledonia, The Origin of the, L. Berland, 904
Spiral Nebulæ: Gravitation and Light Pressure in, Sir Oliver J. Lodge, 702; Nature of the, Prof. Lindemann, 615
Spiranthes Autumnalis, Prof. F. O. Bower, 185; E. P. Smith, J. B. Simpson, 291
Spirit: Photographs, The Case against, C. V. Patrick and W. W. Smith, 139; The Supremacy of, C. A. Richardson, 45; concerning the Review of, C. A. Richardson, 128
Spiritualistic "Phenomena": Cold Light on, An Experiment with the Crewe Circle, H. Price, 139
Spitsbergen: Mites and Rotifers from, 268; the Oxford University Expedition to, Lichens collected by, V. S. Summerhayes, 309
Spleen: The, Bolt and Heeres, 339; Prof. C. Richet, 655, 903; Korenchevsky, 893
Sprengel Pump, A Further Improvement in the, J. J. Manley, 242
Squalodonts, New, from the Miocene of Maryland, R. Kellogg, 824
Stainless Steel, Hardening, Automatic and Electric Furnaces, Ltd., 824
Standard Air, Laws of Variation of the Characteristics of, with Altitude, R. Soreau, 275
Stane Street: The Topography of, a Critical Review of "The Stane Street," by Hilaire Belloc, Capt. W. A. Grant, 630
Star: Maxima and Minima, Variable, for 1923, Dr. L. Campbell, 94; The Interior of a, Prof. A. S. Eddington (May 12), Suppt. v
Stark Effect, Easy Method of observing the, Prof. H. Nagaoka and Y. Sugiura, 431
Stars: A-type, Spectroscopic Parallaxes of, Adams and Joy, 128; Double: Colours and Spectra of, F. C. Leonard, 892; Interferometer Measures of, P. W. Merrill, 27; of Type N, The Radial Motions of, J. H. Moore, 301; Occultations of, by the Moon, 128; O-type, Spectra of Three, Dr. H. H. Plaskett, 580; Parallaxes of Fifty, 94; Radial Velocities of 1013; W. S. Adams and A. H. Joy, 892; Visual Double, The Spectra of, F. C. Leonard, 338
Steam Power Plant Auxiliaries and Accessories, T. Croft, 215
Steatopygous Figures found in France, Dr. R. de Saint-Périer, 786
Steel: Extra Soft, Tempering, at a very High Temperature, M. Sauvageot and H. Delmas, 691; Properties of, Effect of Temperature on Some of the, A. Mallock, 346; Stainless, with Some Consideration of its

Application to the Glass Industry, W. H. Hatfield, 206; Extra Mild at a very High Temperature, Possibility of Tempering, M. Sauvageot and H. Delmas, 762
Steels: Endurance Limit of, H. F. Moore and T. M. Jasper, 788; Magnetism of, H. Pécheux, 795; Special, a Concise Treatise on the Constitution, Manufacture, Working, Heat Treatment, and Applications of Alloy Steels, for Students, Operators, and Users of Special Steels. Chiefly founded on the Researches regarding Alloy Steels of Sir Robert Hadfield, T. H. Burnham, 804
Steers, Under-nutrition and its Influence on the Metabolic Plane of, F. G. Benedict and E. G. Ritzman, 554
Stellar Spectra: of Class S, P. W. Merrill, 372; Unknown Lines in, F. E. Baxandall, 717
Stereoscopic Maps, A New Process for making, G. Poivilliers, 511
Stereoscopy Re-stated, Dr. J. W. French, 726
Sterling Chemistry Laboratory of Yale University, opening of the, and address by Sir Joseph Thomson, 621
Stirling's Theorem: Dr. J. Satterly, 220; J. Strachan, 397; H. E. Soper, 601
Stoat's Winter Pelage, The, Sir Herbert Maxwell, 220; J. Parkin, Dr. J. Ritchie, R. de J. F. Struthers, 360
Stockholm, Technical High School, opening of the new chemistry section of the, 345
Stokes's Law of Fall of a Sphere, Prof. R. A. Millikan, 763, 824
Stonehenge: Concerning the Four Stations, E. H. Stone, 220
Stones, Common: Unconventional Essays in Geology, Prof. G. A. J. Cole, 144
Stonework, Decay in, appointment of a committee upon, 679
Stonyhurst College Observatory, Report for 1922, 822
Storage Organs of Some Seedlings, Structure of the Vascular Supply to the, Prof. H. H. Dixon and N. G. Ball, 275
Stratigraphical Sequence, A Great, L. F. Noble, 480
Stream: Gauging Apparatus, French, 236; -line Filter, Dr. H. S. Hele-Shaw, 689
Stress Distribution in a Rectangular Plate having Two Opposing Edges sheared in Opposite Directions, C. E. Inglis, 725
Stresses in Beams, Rings, and Chains, Prof. E. G. Coker, 161
Structural Units of the Body, The, Dr. E. F. Armstrong, 768
Stuart, Anderson: his relation to Medicine and to the Empire, Dr. R. A. Dart, 111; M.D., Physiologist, Teacher, Builder, Organiser, Citizen, W. Epps, 111
Sub-bacteria, J. E. Barnard, 103
Subject Index to Periodicals, The, E. W. Hulme, 360
Submarine Weathering of Rock-material, K. Humnel, 647
"Sucking-fish," The Adhesive Apparatus of the, Sunder Lal Hora, 668
Sugar Cane: Growth and Maturation of the, Dr. Kuyper, 302; Mealy Bug, The, Prof. T. D. A. Cockerell, 223
Suggestion and Mental Analysis: An Outline of the Theory and Practice of Mind Cure, Dr. W. Brown. Third edition, 803
Suicide Rates, Dr. J. R. Miner, 28
Sulphur: Chloride, The Action of, on Ammonia and on Organic Bases, A. K. Macbeth, 243; Dioxide, The Catalytic Hydrogenation of, Margaret G. Tomkinson, 135; The Removal of, from Metals by Lime, B. Bogitch, 171
"Sumatras" of the Malacca Straits, The, E. E. Benest, 727
Summer Time: 440; in France and Belgium, 477; in France, 509; in Belgium, 543
Sun: Observations of the, made at the Lyons Observatory, J. Guillaume, 35, 452; Total Eclipse of the: September 21, 1922, Dr. W. J. S. Lockyer, 618; at Wallal, Australia, September 21, 1922, Cinema Film of the, 687; Cult, The, in Ancient Egypt, Dr. A. M. Blackman, 499, 536
Sunlight and Disease, Dr. C. W. Saleeby, 574, 891
Sunshine-Recording, G. Gŧablovitz, 650
Sunspot Frequency and the Potential Gradient of Atmospheric Electricity, A Supposed Relationship between, Dr. C. Chree, 242
Superficial Fluids, A. Marcelin, 383
Surface Tension: and Density, a Relation between, D. B. Macleod, 382; and Surface Energy and their Influence on Chemical Phenomena, Dr. R. S. Willows and E. Hatschek. Third edition, 840
Surveying and Navigational Instruments from a Historical Standpoint, Dr. L. C. Martin, 519
Sweden: Geological Research in, 616; Science and Industry in, 851
Swedish National School System, The, Prof. Hänninger, 34
Synchronously Intermittent Light in Industry, The Use of, Dr. J. F. Crowley, 784

Tables: annuelles de constantes et données numériques de chimie, de Physique et de technologie, Vol. IV. Première and Deuxième partie, 493; of $\sqrt{1-r^2}$ and $1-r^2$ for use in Partial Correlation and in Trigonometry, Dr. J. R. Miner, 320; Two-figure, compiled by C. R. G. Cosens, 320
Tactile Vision of Insects and Arachnida, J. P. O'Hea, 498; G. H. Lockett, 570, 848
Tartar Emetics, Action of Light on the, M. Volmar, 831
Tartaric Acid and the Acid Alcohols, The Photolysis of, M. Volmar, 487
Tea Mosquito Bug (Helopeltis theivora *Waterh.*), Factors affecting the Control of the, E. A. Andrews, 875
Tears and the Functions of the Lachrymal Gland, R. Dubois, 654
Technology and Schools, 760
Telephones, the Relative Sensitiveness of, A Comparison of, Prof. C. Barus, 36
Telescopes: before the Early Part of the 19th Century, D. Baxandall, 784; Large, and their Work, Sir Frank Dyson, 447
Temperature: Measurements in Trial Borings 1700 Metres Deep near Molières (Gard), F. Raspal, 275; Radiation from Clouds, A. Defant, 96
Terrestrial Magnetism and the Orientation Faculty of Birds, 711
Tertiary: Brachiopoda of Japan, I. Hayasaka, 647; Brachiopods from Japan, J. W. Jackson, 809; Man in Ipswich, Findings of an International Commission, 157
Tesla Spectra of Complex Compounds, J. K. Marsh and Prof. A. W. Stewart, 115; Prof. V. Henri, J. K. Marsh and Prof. A. W. Stewart, 289
Tetramethylglycerol, Pastureau and H. Bernard, 795
Teutonic Forbears, Our, Prof. F. G. Parsons, 616
Texas, New Eocene Mollusca from, Julia Gardner, 616; Triassic Reptiles and Stegocephalians from, E. C. Case, 129
Thallium: Hydroxide, R. de Forcrand, 554; The Alcoholates of, R. de Forcrand, 135
Therapeutic Inoculation, New Principle of, Sir Almroth Wright and others, 864
Thermal: Conductivity, The Measurement of, No. 1, E. Griffiths and Dr. G. W. C. Kaye, 793; Opalescence in Crystals and the Colour of Ice in Glaciers, Prof. C. V. Raman, 13
Thermionic Valves, Large, Exhibition of, 96
Thermometers, Distance, Negretti and Zambra, 341
Thermopile for measuring Radiation, A, W. J. H. Moll, 622
Thompson, Silvanus, Memorial Lecture, Sir Oliver Lodge, 203
Thorium: Emanation, The Use of, in Inhalation, J. Cluzet and A. Chevallier, 171; Molybdate, $Th(MoO_4)_2$, F. Zambonini, 831; -X, Influence of, on the Catalase of the Liver, A. Maubert, L. Jaloustre, and P. Lemay, 832; Some Effects of, on Diastases and Micro-organisms, J. P. Aversenq, L. Jaloustre, and E. Maurin, 207
Thought and Feeling: The Psychology of, a Conservative Interpretation of Results in Modern Psychology, Dr. C. Platt, 12
Three-body Problem, Periodic Motion in the, Prof. Strömgren, 233
Thunderstorms, Winter, in the British Islands, C. J. P. Cave, 35

Thyroidectomy and Immunity, A. Garibaldi, 763
Tibet: Eastern, Travels of a Consular Officer in, together with a History of the Relations between China, Tibet, and India, E. Teichmann, 491
Tides, The, Dr. Hough, 717
Time Relations in a Dream, Dr. W. R. G. Atkins, 117; H. F. Biggs, 290; M. Gheury de Bray, 361
Tin in the Human Organism, E. Misk, 172
Titanium: in Nile Silt, E. Griffiths-Jones, 346; Hafnium and, Sir T. E. Thorpe, 252; W. L. Fox, 429
"Tom Tower," Christ Church, Oxford. Some Letters of Sr Christopher Wren to John Fell, Bishop of Oxford. Set forth and annotated by W. D. Caröe; with a chapter by Prof. H. H. Turner, and another by A. Cochrane, 838
Torsometer, A Wave-length, and its use with the Universal Interferometer, Dr. A. E. H. Tutton, 725
Tractatus Logico-Philosophicus, L. Wittgenstein, 246
Transformers, Testing, Powerful, 230
Transvaal: bequest to a University or University College in the, for an Agricultural Scholarship by Dame Ella Mabel Farrar, 621; Leguminosæ, Geographical Distribution of some, J. Burtt-Davy, 902
Travel, Memories of, Viscount Bryce, 770
Triboluminescence of some Substances, The Study of the Spectrum of the, H. Longchambon, 452
Trieste and Marine Biology, Dr. M. Stenta, 650
Trinema lineare, Encystation and Reserve Food Formation in, J. S. Dunkerly, 206
Triode Valve in Spectrometry, Use of the, L. Bellingham, 534
Tropical: Agriculture, Educational Problems of, Prof. W. R. Dunlop, 880; Medicine and Hygiene, The Calcutta School of, 550
Trouton's Law, S. B. Mali, 199
True Vertical for all Types of Marine and Aerial Craft, a General Solution of the Problem of finding the, J. G. Gray, 902
Tuberculosis: A New Treatment of, Prof. G. Dreyer, 853; Experimental, on the Rabbit and Guinea-pig, Rôle of the *terrain* in the Evolution of, A. Calmette, A. Bouquet, and L. Nègre, 727; Problems of, 453
Tunneling: Modern, D. W. Brunton and J. A. Davis. (New Chapters on Railroad Tunneling, by J. V. Davis.) Second edition, 494
Tunnelling, Shield and Compressed Air, B. H. M. Hewett and S. Johannesson, 798
Turbines: Reaction, The Yield of, furnished with Aspiration Tubes, M. de Sparre, 587; Steam, Prof. W. J. Goudie. Second edition, 596
Tutankhamen, The Egyptian World in the Time of, Dr. H. R. Hall, 398
Tychonis Brahe Dani: Opera Omnia. Edidit I. L. E. Dreyer. Tomus IV., 179
Typewriting, Stroke in, The Graphical Study of the, J. M. Lahy, 796

Ultramicrometer, The Recording, J. J. Dowling, 487, 742; -microscopy, The Standard Methods of, E. Hatschek, 487; Violet: Absorption Spectra of the Alkaloids of the Isoquinoline Group, The, P. Steiner, 243; Narceine, P. Steiner, 795; Photography of Old Manuscripts, Prof. The. Svedberg and H. Andersson, 130; Spectra of Aniline and the Toluidines, The, F. W. Klingstedt, 243
"Unconscious," Various Meanings of the Term, Prof. C. D. Broad, 587
Universe: The Constitution of the (The Theory of Intersistence), L. Stromeyer, 319; Protest against the Review of, L. Stromeyer, 682
Universities: and Post-War Problems, Sir Robert Horne, 620; and University Colleges of the United Kingdom, Students from Abroad in the, 552; Colleges, etc., Salaries of Teachers in, 829; Conference of, 722; of the Empire, The Yearbook of the, 1923. Edited by W. H. Dawson, 459; Provincial, Sir Theodore Morison, 722; The, and Training for Administrative and Municipal Life, Sir William Beveridge, and others, 722
University: and Secondary Education, 833; College: and Hospital, London, Royal Visit to, 789; London, The Rockefeller Foundation's Gift of the Institute of Anatomy to, 755; Sir Ralph Forster Tablet at, 687; Extension Movement, Jubilee of the, 307; Grants Committee: Returns from Universities and University Colleges in receipt of Treasury Grant, 1921–1922, 899; Students, The Home-residence of, in 1920–1921, 308; Teachers, The Pay of, 58
Upper: Air: Data in America, C. L. Ray, 617; Variables, Correlation of, P. C. Mahalanobis, 684; Winds in India, J. H. Field, 62; Atmosphere: Temperature and Density of the, Prof. F. A. Lindemann and G. M. Dobson, 646; The High Temperature of the, Prof. F. A. Lindemann and G. M. B. Dobson, 256; as an Explanation of Zones of Audibility, F. J. W. Whipple, 187; Cretaceous Dinosauria from Alberta, C. W. Gilmore, 719; Ordovician Rocks of the South-western Berwyn Hills, The, W. B. R. King, 794
Ur, Excavations at, 336, 369; C. L. Woolley, 508
Uranium Salts under the Influence of Light, The Oxidations and Reductions produced by, M. Aloy and M. Valdiguié, 727
Urbain's Celtium Lines, On, H. M. Hansen and S. Werner, 461
Ureas, the Tetrasubstituted, A New Preparation of, A. Mailhe, 554
Urease, Dr. W. R. Fearon, 894
U.S.A.: admission of bulbs into the, 267; and Canada, Dental Education in the, 792; Army Intelligence Tests, Social Significance of, Prof. P. E. Davidson, 442; Astronomy in the, 546; Bureau of Standards, Dr. G. K. Burgess appointed director of the, 819; Commissioner of Education of the, Report of, for 1921–22, 865; Education Week in the, 621; Geodetic Survey, Annual Report, 1922, 548; Helium in the, Dr. R. B. Moore, 88; National Academy of Sciences: award of the Comstock prize to Prof. W. Duane, and the Mary Clark Thompson gold medal to Dr. E. de Margerie, 716; election of officers, 716; Palæocene Primates of the, J. W. Gidley, 893; Peat in the, E. K. Soper and C. C. Osborn, 582; Secondary Schools in the, Examination and Inspection of; The Rising Cost of Education in the, 652; Sex Education in High Schools of the, 66; South-western, Land Mollusca of the, Dr. H. A. Pilsbry, 786; Students in Universities, Colleges, and Professional Schools in the, 345; Summer Schools in the, 33; Western, Guide-book of the, Part F., M. B. Campbell, 545

Vacuum: Device, A Simple Regenerative, and some of its Applications, H. P. Waran, 691: Gravitation Needle, The Equilibrium Positions of the, Prof. C. Barus, 36
Valences, Positive and Negative, Prof. W. A. Noyes, 161
Valve-maintained Fork as a Precision Time Standard, The, D. W. Dye, 242
Vanadium Pentoxide Sol, The Double Refraction due to Motion of a, and some Applications, R. H. Humphry, 623
Vanillin, Determination of the Purity of, S. B. Phillips, 419
Vapeur, Production économique de la, Dr. O. Manville, 565
Vaporisation, The Latent Heat of, etc., E. Mathias, Dr. C. A. Crommelin, and Prof. H. Kamerlingh Onnes, 587
Vapour Pressure and Density of Sodium Chloride Solutions, W. R. and C. Elspeth Bousfield, 622
Variable with a Remarkable Spectrum, Dr. H. Shapley, 615
Vector Analysis: and the Theory of Relativity, Prof. F. D. Murnaghan, 697; of Four Dimensions, A Generalised, H. T. Flint, 419
Vegetable Mass, A Dried, made from a Variety of Wild Plants, Chenopodium and others, G. H. Wilkins, 206
Vegetation: der Erde, Die, Herausgegeben von Prof. A. Engler und Prof. O. Drude. XIV. The Vegetation of New Zealand, Dr. L. Cockayne, 457; in the Channel according to the Dredgings carried out by the *Pourquoi-Pas?* The Limit of, G. Hamel, 867

Venus, The Atmosphere of, Prof. St. John and G. B. Nicholson, 301
Veratrol and Vanillin, The Ultra-violet Absorption of, P. Steiner, 488
Vertical: Beam, "Artificial," Prof. W. C. Baker, 185; Dimensions, Measurement of, with Microscope, F. Addey, 236; Systems, The Growth and Decay of, S. Fujiwhara, 309
Vesta, 479
Veterinary Medicine, Surgery, and Obstetrics, Encyclopædia of, edited by Prof. G. H. Wooldridge. 2 vols., 664
Victoria, the National Herbarium of, Contributions from, No. 3, J. R. Tovey and P. F. Morris, 311
Victorian Memoirs and Memories, Lord Ernle, 611
Vienna University, Prof. E. W. Scripture appointed honorary professor of experimental phonetics, 552
Virus Diseases of Plants, Dr. E. J. Butler, 551
Viscosity: Neutralisation, and Isomorphism, L. J. Simon, 347; of a Liquid and its Coefficient of Expansion, A Relation between the, D. B. Macleod, 382; of Liquid Mixtures showing Maxima, The, D. B. Macleod, 382
Viscous Fluid, Infinite, The Steady Motion of a Cylinder through, A. Berry and Lorna M. Swain, 205
Vision: and Light Sensitiveness, J. P. O'Hea, 705; The Laws of, and the Technique of Art, A. Ames, C. A. Proctor, and Miss Blanche Ames, 581
Visual: Illusions: their Causes, Characteristics, and Applications, M. Luckiesh, 876; Perception, The Delay of, F. G. Smith, 648
Vitalism and Anti-Vitalism, Prof. E. W. MacBride, 72
Vitamin-A, The Formation of, Miss Katharine H. Coward, 858
Vivireaction in Biology and Pathology, The Law of, J. Amar, 554
Voice Beautiful in Speech and Song, concerning the review of, E. G. White, 159
Volcanic: Activity in Iceland and Long Distance Transport of "Dust," J. N. Carruthers, 255; Dust and Climatic Change, Prof. W. J. Humphreys, 431; Island, Formation of a New, South of Poulo-Cécir de Mer, M. Pélissier, 831
Voltage Regulator, An Automatic, Isenthal and Co., Ltd., 62
Volume and Refractive Index, Changes of, associated with (*a*) the Formation of Organosols and Gels; (*b*) the Reversible Sol to Gel Transition, E. W. J. Mardles, 170
Vowel Sounds, Artificial, The Production of, Sir Richard Paget, 205

Wales, University of, Gift to, by D. Radcliffe, 205
War, Hygiene of the. Edited by Maj.-Gen. Sir W. G. Macpherson, Col. Sir W. H. Horrocks, and Maj.-Gen. W. W. O. Beveridge. Vols. 1 and 2, 626
Warialda Meteorite of N.S.W., The, J. C. H. Mingaye, 374
Warrington Museum, Report of the, G. A. Dunlop, 158
Washington Academy of Sciences, election of honorary foreign members of the, 783
Water: in the Atmosphere, The, Dr. G. C. Simpson, Supplement (April 14), v; in the Chalk, The Circulation of, F. Diénert, 347; Molecule, An Interesting Property of the, Prof. A. P. Laurie, 830; Policy, A National, 349; Power: in India, J. W. Meares, 96; in the British Empire, T. Stevens, 607; Snails and Liver Flukes, A. W. Stelfox; Dr. Monica Taylor, 49; Supply, appointment of a standing advisory committee on, 126
Waterspouts, D. Brunt; H. E. Hornby, 82
Wave: -power Transmission, W. Dinwiddie, 417; Resistance, Studies in, Prof. T. H. Havelock, 725; Theory, The, and the Quantum Theory, Prof. C. G. Darwin, 771
Waves, Maintained, The Propagation of, along an Iron Wire, G. Laville, 654
Waxwing, Migrations of the. Dr. J. Ritchie, 511
Weather: the, 819; Forecasting in the North Atlantic and Home Waters for Seamen, Com. L. A. Brooke-Smith, 107; of 1922, The, 127; of Great Britain, December 3, 1922 to March 3, 1923, 370; Research on the Kermadec Islands, D. C. Bates, 648
Weevil, The Life of the, J. H. Fabre. Translated by A. Teixeira de Mattos, 216
Wegener's Hypothesis: of Continental Drift, P. Lake, 226; Dr. J. W. Evans, 393; Dr. J. W. Evans, W. B. Wright, and others, 30; Botanical Aspects of, Prof. R. H. Compton; the Writer of the Article, 533; and the Great Pyramid, Dr. G. P. Bidder, 428; Prof. W. M. F. Petrie, 429; and the Origin of the Oceans, T. Crook, 255; The Distribution of Life in the Southern Hemisphere, and its Bearing on, K. H. Barnard and others, 131; The Life-Cycle of the Eel in Relation to, Dr. T. W. Fulton, 359; Dr. A. M. Davies, 496; The Zwartebergen and, W. B. Wright, 569
Weight, Changes in, of the Organs of the Pigeon in the Course of B-avitaminosis, J. Lopez-Lomba, 796
Weights: and Measures, with some Geophysics, Dr. G. C. Simpson, 558; Measures, and Coinage, Confusion in, 508
Wellington, N.Z., Victoria College, Gift to, by Sir Walter Buchanan, 518
Wembley Laboratories, Physics in Industry at the, 344
Wet Bulb Temperatures and Thermodynamics, Dr. C. W. B. Normand, 28
Whaling Problem, Scientific Investigation of the, Sir Sidney F. Harmer, 540
Wheat: Genetics and the History of, Drs. K. Sax and J. W. Gowen, 547; Influence of the Rainfall during the "Critical Period" of, on the Yield, J. Beauverie, 452; Rust and Climate, Relations existing between the Development of, J. Beauverie, 383
Whitworth Society, Inauguration of the, Dr. Hele-Shaw elected president, 92
Wien Bridge, Use of the, for the Measurement of the Losses in Dielectrics at High Voltages, with special reference to Electric Cables, A. Rosen, 829
Willoughby, Charles, Fellow of the King and Queen's College of Physicians, T. P. C. Kirkpatrick, 243
Wimbledon Common, protest against a proposed by-pass road adjacent to, 889
Wind: and Tropical Cyclones, Vertical Change of, S. K. Banerji, 668; Sir Napier Shaw, 702; and Weather, Prof. A. McAdie, 597; Steadiness in the Upper Air, H. Harries, 583; the Instantaneous Direction of the, An Apparatus giving, Huguenard, Magnan, and A. Planiol, 452; Theory of the Measurement of, by shooting Spheres upward, L. F. Richardson, 241
Winds and of Barometric Pressures, Effects of, on the Great Lakes, J. F. Hayford, 45
Wine, The Preparation of, by Continuous Fermentation, L. Semichon, 655
Wired Wireless, An Electro-capillary Relay for, C. E. Prince, 242
Wireless: Communication, The Origin or Basis of, Sir Oliver Lodge, 328; Direction and Position Finding by, R. Keen, 628; Licences, Broadcasting and, 589; Popular and Concise, Lt.-Col. C. G. C. NOTICE.

The present issue of NATURE begins a new volume; the time is therefore opportune to begin subscriptions. The subscription rates are to be found on p. vii.

Proof copies of the accompanying photogravure plate portrait of Prof. Lorentz, suitable for framing, are obtainable for 5s., or by post for 5s. 6d.

OFFICE OF NATURE,
ST. MARTIN'S STREET, W.C.2.

THE SIR JOHN CASS TECHNICAL INSTITUTE,

Jewry Street, Aldgate, E.C.3.

THE following Special Courses of Instruction will be given during the Lent Term, 1923:—

THE MATHEMATICAL THEORY AND APPLICATIONS OF STATISTICS.

By E. C. SNOW, M.A., D.Sc.

A Course of Ten Lectures on the modern mathematical methods of dealing with statistical data in social, educational, economic, meteorological and medical problems, suitable to teachers and to students of economics, meteorology and medicine. Facilities will be given to students who wish to undertake special investigations and research work on subjects associated with the course of instruction.

Fridays, from 7 to 9 P.M.

The First Lecture of the Course will be given on **Friday, January 12, 1923.**

ALTERNATING CURRENTS AND ELECTRICAL OSCILLATIONS.

By D. OWEN, B.A., D.Sc., F.Inst.P.

A Course of Ten Lectures accompanied by Practical Demonstrations, and intended for post-graduate students and those otherwise qualified to pursue this branch of electrical science and its applications in wireless telegraphy and telephony.

Tuesdays, from 7 to 8.30 P.M.

The First Lecture of the Course will be given on **Tuesday, January 9, 1923.**

Detailed Syllabus of the Courses may be had upon application to the Office of the Institute, or by letter to the PRINCIPAL, CHARLES A. KEANE, D.Sc., Ph.D., F.I.C.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY,

SOUTH KENSINGTON, S.W.7.

DEPARTMENT OF OPTICAL ENGINEERING AND APPLIED OPTICS.

The usual Classes are being continued during the SPRING TERM, and in addition the following will be given:—

COLOUR AND ITS MEASUREMENT.—A Course of TEN Weekly Experimental Lectures beginning on Tuesday, January 16, at 6.30 P.M. will be given by Dr. L. C. MARTIN.

THE MECHANICAL DESIGN OF THE COMMON MICROSCOPE.—A Course of SIX Weekly Lectures will be given by Professor POLLARD on Thursday at 6 P.M., commencing January 18.

For further particulars and for admission tickets apply to the REGISTRAR at the above address.

The Director is open to receive applications from students and others desirous of carrying out research work in the Laboratories.

THE GENERAL DISCUSSIONS OF THE FARADAY SOCIETY.

The SECRETARY will send on application the latest list of available REPRINTS.—10 Essex Street, London, W.C.2.

CHELSEA POLYTECHNIC,

CHELSEA, S.W.3.

Day and Evening Courses in Science under Recognised Teachers of London University.

I. **INDUSTRIAL CHEMISTRY DEPARTMENT.** Technical Courses in Analytical and Manufacturing Chemistry, Pharmacy, Food and Drugs, A.I.C. Courses, Metallurgy, Assaying, Foundry Work, Research.

II. **INDUSTRIAL PHYSICS DEPARTMENT.** Practical work in General Physics, Applications to Industries, Metrology, Calorimetry, Illumination, Acoustics, Electrical Measurement, Research.

III. **BIOLOGICAL AND GEOLOGICAL DEPARTMENT.** Courses for B.Sc., etc., in Botany, Geology, Mineralogy, Zoology, Special Courses in Bio-chemistry, Bio-physics, Bacteriology, Physiology, Hygiene, Entomology, Plant Pathology. Course for Tropical Planters, Research.

Lent Term begins January 9, 1923.

SIDNEY SKINNER, M.A.
Principal.

Telephone: Kensington 809.

BIRKBECK COLLEGE.

(UNIVERSITY OF LONDON.)

Principal—GEORGE SENTER, D.Sc., Ph.D., F.I.C.

EVENING COURSES for the Degrees of the University of London in the Faculty of Science and for the Geography Diploma.

Facilities are also provided during both day and evening for Post-Graduate and Research Work.

Calendar, 1s.; by post, 1s. 5d. Prospectus free.

For full particulars, apply to the SECRETARY, Birkbeck College, Fetter Lane, E.C.4.

BATTERSEA POLYTECHNIC.

Principal—* ROBERT H. PICKARD, D.Sc., F.R.S.

University Courses, day and evening, under Recognised Teachers of the University of London are provided in Science, Engineering and Music.

CHEMISTRY.—*J. KENYON, D.Sc., F.I.C.; *J. L. WHITE, D.Sc.
PHYSICS.—*S. MARSH, B.Sc., Ph.D.; *A. E. EVANS, B.Sc.; *J. F. PHILLIPS, B.A., B.Sc.
MATHEMATICS.—*F. M. SAXELBY, M.Sc., B.A.; *F. W. HARVEY, B.Sc., M.A.; *W. G. BICKLEY, M.Sc.
MECHANICAL AND CIVIL ENGINEERING.—*W. E. M. CURNOCK, M.Sc., B.Eng.; *J. B. SHAW, A.R.C.S., Wh.Ex.; *H. M. EDMONDS, B.Sc.; *V. C. DAVIES, B.Sc., A.M.I.Mech.E.
ELECTRICAL ENGINEERING.—*A. T. DOVER, M.I.E.E., A.Am.I.E.E.; *H. C. MANN, A.M.I.E.E.; *H. W. HARTRIDGE, A.M.I.M.E.; *A. M. PARKINSON, B.Sc., Eng.
MUSIC.—* H. D. WETTON, Mus. Doc., F.R.C.O.

* Denotes recognised teacher of University of London.

There are also:—

Day Technical College in Engineering and Science. Day Training College of Domestic Science. Day Department of Hygiene and Physiology. Day School of Art and Crafts.

Evening Courses in Engineering, Chemistry, Physics, Mathematics, Bacteriology, Chemical Engineering, Hygiene and Physiology, Art, Matriculation Subjects, Domestic Economy, Music, Physical Training.

Hostels for Women Students. Large playing fields at Merton.

APPOINTMENTS BOARD

OF THE

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY,

SOUTH KENSINGTON, S.W.7.

EMPLOYERS requiring men who have received a thorough training in Science and Technology, and who are Diplomates or Associates of the Imperial College, or of one of its three constituent Colleges, are asked to make use of the services of the Board. No fees.

The Imperial College includes The Royal College of Science, The Royal School of Mines, and The City and Guilds (Engineering) College. The Associates of the Colleges receive thorough training in Science and Technology, including Aeronautics, Applied Optics and Optical Engineering, Biology, Chemical Technology, Chemistry (all branches), Engineering (all branches, including Metallurgy, Mining, Mining Geology and Oil Technology), Geology, Mathematics and Mechanics, and Physics.

B.Sc. (LADY) wishes post as junior assistant in chemistry laboratory or as chemistry demonstrator. 6 months' experience. Box 43, c/o NATURE Office.

Scientific Worthies.

XLII.—HENDRIK ANTOON LORENTZ.

THE outstanding leader in physical science who is the subject of this notice was born at Arnheim in Holland on July 18, 1853, graduated at Leyden in 1875, became Professor of Mathematical Physics at that University as early as 1878, discharged the duties of that Chair with great brilliancy until his appointment a few years ago to the direction for research in the historical Teyler Institute at Haarlem, leaving Ehrenfest as his successor. He retains his connexion with Leyden as Honorary Professor, and does not treat that position as a sinecure: the weekly lecture delivered by him, and usually reported for publication by members of his audience, is one of the outstanding events in the University life. At Haarlem he leads the philosophic life, enjoying the society of his grandchildren, controlling the physical side of the Institute, which is also famous on the artistic side for the collection of the great local painter Franz Hals. The jubilee of his doctorate on December 11, 1900, was commemorated by the presentation of a volume of researches contributed by most of the notable cultivators of physical science in the world.

Since the middle ages the Low Countries have always been a seat of fervent and productive intellectual activity. In early times they were conspicuous for a broadening of the Catholic theological learning in the direction of humanism. Later, in the congenial soil provided by the achievement of ordered political liberty, they became a focus of Protestant learning, which under the stimulus of free controversy broadened out into the domains of Jurisprudence and Polity. Holland was the peaceful refuge of students such as Descartes and Spinoza: its free press played a principal part in the spread of learning in Europe, and was even

the means of original publication of some of the writings of Galileo. In physical science Huygens was one of an illustrious international company which included his contemporary Newton, and ranks next among his peers both in dynamics and in optics. In our own days the eminence of Holland in physical science is maintained by H. A. Lorentz, H. Kamerlingh Onnes, P. Zeeman, and others of a brilliant band who have been, in the main, products of the great University of Leyden which dates from the times of national revival.

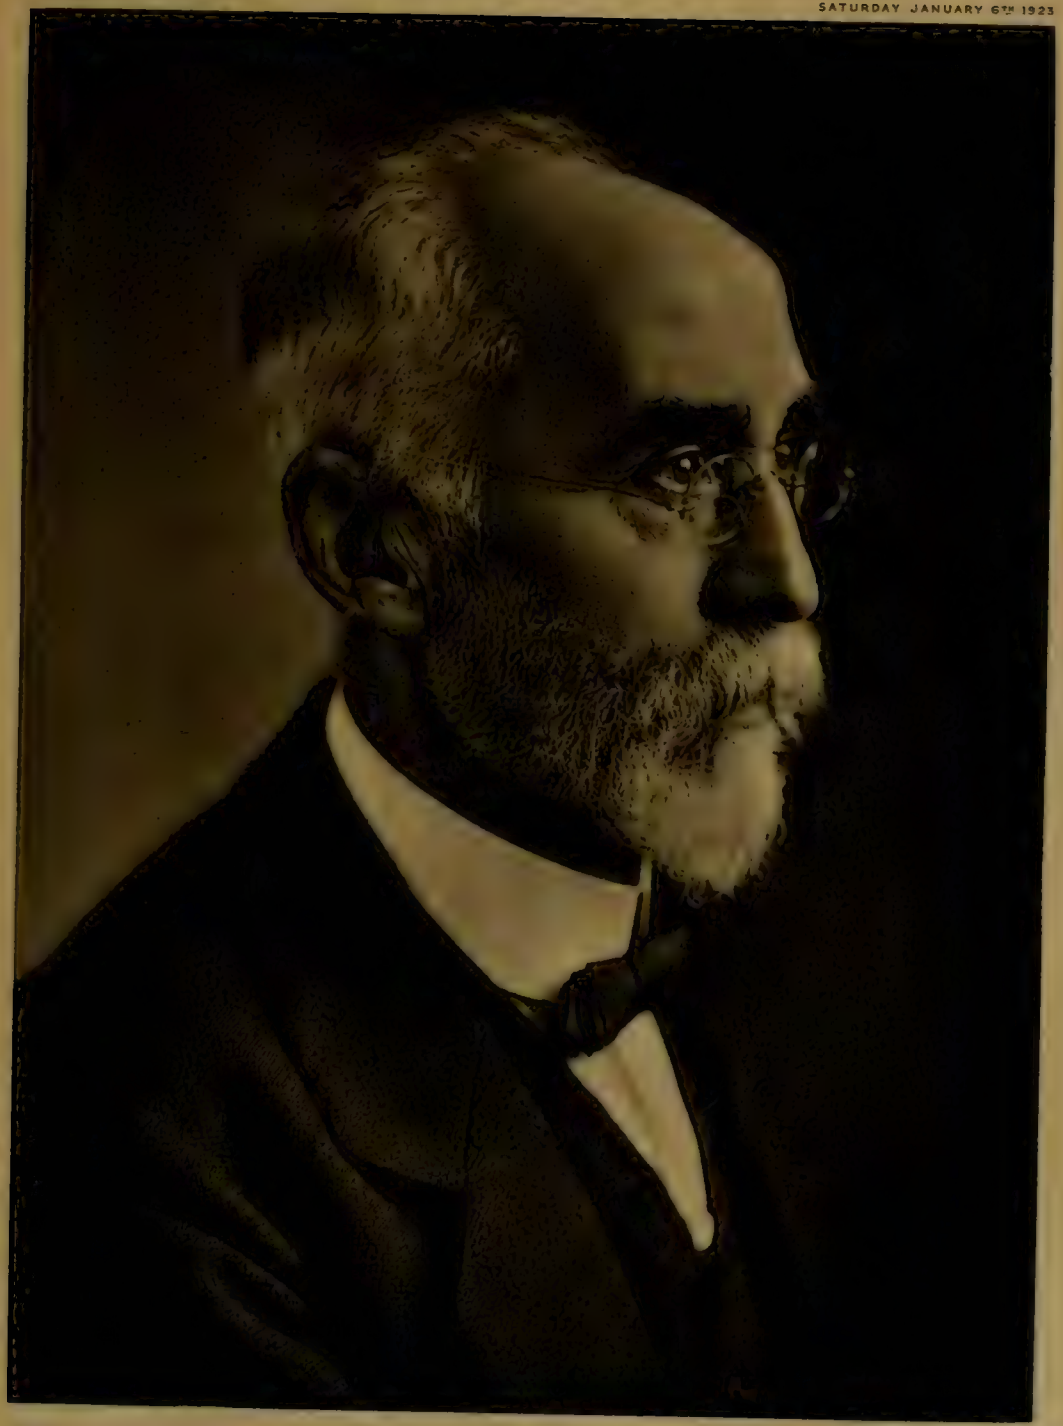
In his early days contemporaries in this country to whom Dutch sources were not very accessible owed their knowledge of Prof. Lorentz's writings mainly to expositions and discussions by a kindred spirit the late Lord Rayleigh, and subsequently by Lodge in connexion with his thorough experimental scrutiny of the relation of the Earth's motion to the aether, regarded as the seat of propagation of the rays of light by which we explore the universe. No trace could be anywhere found of exception to the principle that Lorentz favoured as the basis of optical theory, that the aether is a stationary medium: material bodies must thus be structures of molecular texture so open that, in the simile of Thomas Young when he pleaded in 1800 for a revival of the wave theory of Huygens, the aether penetrates through moving matter as freely as the wind through a grove of trees. The republication of some of Prof. Lorentz's early investigations, in which historical exposition and criticism are so happily blended with new advance, in vol. i. of his "Abhandlungen über theoretische Physik" in 1907 revealed, at any rate to one student, how much research into sources might have been saved him by earlier access to the *Archives néerlandaises* of 1887.[1] The volume also presented much unpublished material. There is for example a treatise on the Second Law of Thermodynamics and its relation to Molecular Theory, pp. 202-298. Nothing could be more valuable, for students who desire a real grasp of this fascinating subject, than connected exposition by a master, on general lines freed from excursions into detail.

This work was doubtless even fresher then than now, when the principles the scope of which is so universal have been sifted and refined in all directions in so many essays and text-books. The power and simplicity of the foundations of pure thermodynamics have at all times been a magnet to the most powerful minds, from Kelvin who persisted with the prescience of genius in hunting out and rediscovering in Paris the master tract of Sadi Carnot, down through Clausius, Maxwell, Helmholtz, Willard Gibbs. One can recall the crucial fundamental concept of Available, in contrast with Dissipated, Energy, introduced in a fragmentary way by Kelvin, whose wealth of fresh thoughts and of practical interests scarcely ever allowed him a chance of systematically developing any subject; its relation to the more convenient analytical concept of Entropy introduced by Clausius, and its physical elucidation in terms of a science of molecular statistics by Boltzmann and Gibbs; the luminous expositions and developments of Rayleigh; the theoretical outlook of Gibbs, vast enough to predict a full-blown new science of Physical Chemistry before it had come to birth; even such questions of pure logic as the intimate essential connexion of the principle of Carnot with the identification of heat as energy which came finally twenty years later. One remembers a remark of Prof. Lorentz in relation to an obituary exposition of Kelvin's early activity, that he had not been aware that this side of the subject had been so fully grasped at that early date.

In this historical feeling which has led Prof. Lorentz so frequently to interweave his own contributions to knowledge into a reasoned analysis of the actual position of the science at the time, close affinity may be traced with the work of Lord Rayleigh. For both of them, perhaps especially for the latter, an essential interest of human learning is the story of its historical evolution: nothing is so attractive as to recognise, still more to discover, the early insight of genius into problems usually thought to belong to later times. To both of them it appears to have been at least as congenial to explore and improve a wide field of knowledge, as to engage in strenuous special calculations such as are the very essence of progress in dynamical astronomy: though neither of them shirked such tasks when they presented themselves. Perhaps nowadays appreciation of the past is more than ever necessary to balance the haste of the present.

Of late years Prof. Lorentz's activity has been much turned by public demands into the direction of formal courses of lectures at University centres, in which his own thoughts and ideas are happily embedded. Thus the standard treatise on the Theory of Electrons arose out of lectures at Columbia University, New York, in 1905; several courses have been published in German; and a most interesting and concise reasoned account of the state of knowledge and speculation regarding statistical thermodynamic theories, leading up through Brownian movements and local fluctuations of energy into the mysteries of quanta, delivered at the Collège de France in 1912, came to be issued in French from Leipzig with additional notes in the year 1916. Earlier discussions on this latter subject (Abhandlungen, vol. i.) followed the lines developed also

[1] "Influence du mouvement de la terre sur les phénomènes lumineux": Abhandlungen, i. pp. 341-394.



H. A. Lorentz

by Maxwell, Boltzmann, Rayleigh, Gibbs, which originated this domain of knowledge and, though now beset with fundamental experimental difficulties, are still the ultimate foundation of our ideas. The articles "Maxwells Electromagnetische Theorie" (June 1903) and "Elektronentheorie" (December 1903) in the Mathematical Encyclopædia are standard treatises.

His doctor's dissertation (1875) was a treatise (177 pp.) on the reflection and refraction of light, which was abstracted at considerable length by E. Wiedemann in his *Beiblätter*, vol. i., 1887. Proceeding from Helmholtz's form of the Maxwell theory, it develops a hint contained in a footnote in Helmholtz's first memoir, that the interfacial conditions of the electric theory are precisely those that lead naturally to Fresnel's standard laws of reflection. Transmission in metals also comes under review, and the laws of reflection from their surfaces; following up Maxwell's remark that gold leaf is far more transparent for the rapid electric alternations in light than its steady electric resistance would lead one to expect. It is curious that Maxwell himself has nowhere indicated the application of his theory to the dynamically fundamental subject of reflection. In a letter of 1864 to Stokes [2] in which he hints at his electric theory, then taking form, he remarks: "I am trying to understand the conditions at a surface for reflection and refraction, but they may not be the same for the period of vibration of light and for experiments made at leisure."

Other early papers published in Dutch, and reported in the *Beiblätter* by long abstracts, include a discussion of the propagation of sound according to the kinetic theory of gases (1880), and a note (1882), stimulated by a discussion of Korteweg, on formulæ for the interaction between two electrodynamic elements constructed after the manner of that of Ampère.

The famous memoir in which he applied for the first time considerations relating to discrete molecules to electric propagation in material bodies, and incidentally arrived at a rational refraction-equivalent $(\mu^2-1)/(\mu^2+2)\rho$ for each substance, independent of its density, is abstracted by himself in *Annalen der Physik*, ix., 1880, pp. 641-684. Here again the version of Maxwell's theory developed in the first of Helmholtz's critical memoirs (1870) is followed, possibly as being more accessible outside England. Indeed the expression for the refraction-equivalent is largely independent of any particular theory of propagation in the molecular medium; as is illustrated by the fact that his formula was identical with a result deduced ten years earlier in Danish on lines of elastic solid theory by his namesake L. Lorenz. The discussion of its range verified the rough substantial invariance of this expression even for change from the gaseous to the liquid state, and showed that it provides an additional atomic constant persisting through many types of chemical bonding of the atoms. This is now of course a large domain in physical chemistry.

The contribution of a vibrating molecule to the radiation is treated, after the manner of the general Stokes-Kirchhoff equations, in close correspondence as it happens with the familiar later formulation of Hertz for a dipole vibrator emitting electric radiation. Extension to include optical dispersion is considered. The result, already known to the masters, is enforced that Cauchy's statical theory which ascribed dispersion to a sensible value of the ratio of molecular distance to wave-length, is for actual matter entirely insufficient, unless as he remarks the laws of attraction are quite changed at molecular distances: but its effect is not absolutely null, and it is pointed out that cubic crystals, which are isotropic on Maxwell's theory, should on this account exhibit a small secondary double refraction of very symmetric type. Recently Prof. Lorentz has returned to this topic, and announced the detection of this quality, amidst others due perhaps to imperfection of the crystal, in his laboratory at the Teyler Institute. The detailed investigations of Rayleigh (1892) on atomic obstacles arranged in lattices stop short of the approximation here required. Later both Lorentz and Rayleigh noted that a perfect crystal should not scatter at all the light passing through it.

A static theory being thus inadequate, dispersion has to be ascribed to resonant vibration excited in the molecular structures. He works out as an example the very simplest ideal case, that of an electric charge e attracted to a massive nucleus by elastic force proportional to distance; which is the identical illustration that served him nearly twenty years later to elucidate the Zeeman magnetic spectral effect and the polarisation of the emitted radiation. The result of course also provides an illustration of the anomalous or selective refraction discovered by Kundt, which he does not then notice, restrained possibly by our ignorance which he remarks of the actual structure of molecules. Nowadays the argument for the Lorentz refraction-equivalent is made almost intuitive by correlating it with the equivalent $(K-1)/(K+2)\rho$ for the dielectric inductance K, usually ascribed to Mosotti and to Clausius. No demonstration could however be simpler than the one given even earlier by Maxwell in 1873 for the cognate problem of the conductance of a medium filled with small spheres of different material: "Elec. and Mag." i., § 314.

In 1884 Prof. Lorentz directed his attention to the

[2] "Scientific Correspondence of Sir George Stokes," vol. ii. p. 26

effect which magnetisation exerts on the polarisation of reflected light, discovered by Kerr in 1878, and discussed immediately after on the basis of general theory by FitzGerald but only for transparent media. A magneto-optic constant had to be introduced for each metal, naturally of complex type, which might be regarded as continuous with the constant of the Hall effect for a steady field. Experimental research, based on his formulæ, was started in the laboratory of Prof. Kamerlingh Onnes by Sissingh in 1886, in collaboration from 1889 with Zeeman: and their results are finally reported in *Archives néerlandaises*, 1894. Everything connected with magneto-optics excited great interest in England from the time of Faraday's fundamental discovery, and the stimulating dynamical speculations of Kelvin (and Maxwell, "Elec. and Mag." ii.) connecting it with a rotatory molecular theory of magnetism. The discovery of Kerr intensified the interest. The very exact material provided by Sissingh and by Zeeman was available as a test for a concentrated theoretical formulation. One may be permitted to claim that the most systematic theoretical development and thorough verification of the subject, remarkably consistent on all sides, is in a Cambridge Fellowship dissertation by J. G. Leathem, Phil. Trans., 1897, pp. 89-127, which has scarcely received the attention that it deserves. This theory attains even to features of exact prediction, which had been anticipated in a dissertation in Dutch by C. H. Wind shortly before.

About 1897 came the cardinal discovery of the effect of a magnetic field on spectra, by Zeeman, which was worked out in the early stages in the light of Lorentz's theoretical guidance. As already remarked, the elementary illustration by a single vibrating ion under elastic control, which covers all the normal features of the Zeeman subdivision, had been used to illustrate optical dispersion long before. The results admit of easy extension to any system of electrons describing interacting free orbits, however complex, about a massive positive nucleus. When there are more than three components in a spectral line, the vibrating system must be more complex. The application of the theory of the small vibrations of general dynamical systems, which suggests itself at once, gave no help and it was scarcely to be expected that it would. Recent schematic solutions employing the language of quasi-periodic systems are said to cover thoroughly the whole ground: it would be most interesting to have Prof. Lorentz's reasoned views on the promise held out by this rather inscrutable type of analysis. One observes that he uses here as elsewhere the well-tried method of discussion by mirror images, to fix the types of symmetry (cf. *Astrophys. J.* 1899): the magnetic field is reversed in the image in order to avoid change of signs of all the charges, which would lead to negative nuclei and positive electrons.

There is a paper of 1892 in *Ann. der Physik* on refraction across thin metal prisms, in which one discovers a discussion of an essential point often sought for, namely, the influence on the direction of propagation by rays of the steep gradient of amplitude along the phase-front of the emergent train. The introduction to this paper is on lines now strangely familiar; an investigation of what type of differential equations one is formally restricted to by the principle of invariance alone, in order to give rise to simple trains of damped undulations in an isotropic absorbing medium.

We come now to the two famous memoirs "La Théorie électromagnétique de Maxwell et son application aux corps mouvants," *Archives néerlandaises* 1892 (pp. 189) and "Versuch einer Theorie der elektrischen und optischen Erscheinungen in bewegten Körpern," 1895 (pp. 139), both published as separate treatises. Both of them proved to be very difficult, in comparison with previous memoirs on cognate matters, partly on account of the strangeness and complexity of the notation and analytical processes to English readers saturated with Maxwell's notation and his more intuitive procedure. One might perhaps guess that both of them were worked up gradually, as seems to have been Prof. Lorentz's custom, out of professorial lectures: for they include digests of previous papers. The main feature in both is the expansion of the Maxwell theory on the basis of mobile elementary ions, regarded simply as coherent volume distributions of electricity, as the sources of the field. That point of view had already been clearly expressed in the paper of 1878–80 on refraction-equivalents and incidentally on the explanation of dispersion, but was then developed more in terms of attractions at a distance after Helmholtz. As regards the dynamical side, both memoirs proceed through the principle of d'Alembert in a form which makes it to some extent a substitute for minimal Action. Looking through them in the light of to-day the second, which appeared early in 1895 and referred largely to optical phenomena, seems much the more striking. Thus he recognises that the Maxwell stress for free space does not balance when the state of the system is not steady, unless a quantity which Poincaré afterwards described as a distribution of a momentum connected with the stress is taken into account: this was the beginning of the stress-energy-momentum tensor. The correction in the Fresnel convection-coefficient for transparent media is obtained, arising from dispersion, which in recent years Zeeman has fully verified. All kinds of optical convective phenomena are closely considered.

But the main result is the establishment of a systematic correspondence between the electrodynamic fields of a material system at rest in the aether and the same system convected with a uniform velocity v. The result in its simple form holds only up to the first order of v/c. The fields are not identical, unless certain of the vectors are ignored as being unreal and merely mathematical expressions. But he points out that all relations concerned with the interactions of matter, such as alone experiment could test, are unchanged by the convection. This is the first systematic appearance of the electrodynamic principle of relativity. It can be extended in modified form with confidence to the second order of v/c, at any rate on an electric theory of matter, for the electrons within the atom are still small enough compared to their distances apart to be treated as point charges; and that covers the whole practical field except the domain of β rays. But when, as Prof. Lorentz noted in 1904, the truth of the result as thus extended is found to hold for the field up to all orders, the completion of this exact correspondence to include the atomic structure has to become a postulate or assumption: that was the birth of the modern efforts towards unrestricted convective relativity as an abstract formulation holding far beyond experimental verification.

There is a striking formal analysis near the end for the effect of convection on rotational optical media. For an isotropic medium the ordinary rotational modulus will be altered, and also a new rotational effect involving interaction of the vector velocity of convection with the vectors of the field can arise. As the result is of the first order in v/c, it is difficult to see how it could exist on a purely electric theory of atomic structure; so that the two formal effects should cancel. It appears that the experiments of Mascart (1872) were scarcely adequate to verify this absence of effect. Anyhow the principle of electrodynamic relativity repudiates any effect altogether.

Hitherto the transformation, up to the second order, for convection was ascribed to the molecular system, the frame of reference of space and time remaining invariable. For steady states of the system, in which time does not come into consideration, it meant a shrinkage along the direction of convection: changes so rapid that the alteration of the measure of time could be effective scarcely occurred, and were put aside. When Prof. Lorentz pointed out that the transformation, which is now known by his name, was exact as regards electrodynamic fields in free space, and also exact to some extent when there are electric densities in the field, the subject took on a new and wider trend. The transformation was transferred by Einstein (in recent years attached to Leyden as part-time Professor) to the frame of space and time instead of the molecular aggregations of matter, each taken separately, which accidentally occupied it. The question is then no longer confined to shrinkage of the material frames of terrestrial experiments: effects must be expected over astronomical distances across empty space. Adaptation of the Newtonian law of gravitation into a form invariant for the fourfold space-time frame of Minkowski, which was the final analytical consolidation of this aspect of the subject, was effected by Lorentz and by others with a view to search for astronomical indications, and in particular to find out whether the outstanding minute secular rotation of the orbit of the planet Mercury, already the standard test for modified laws of gravitation, became amenable. The changes thereby introduced proved to be of small account.

Meantime Einstein seems to have been struggling to get rid of the Minkowskian uniform universal space-time, which was just as absolute in its combined four dimensions as was the Newtonian scheme of separate space and time. By identifying locally the essential features of a physical field with intrinsic differential constructs in the fourfold expanse, named tensors, of which a formal calculus had already been fully developed by Ricci and Levi-Civita, he was able finally to select a group of related local tensors as the result of tentative adaptations so as to exhibit the now famous view of gravitation as represented by warping of the fourfold pseudo-spatial expanse around the material nuclei. Though this can scarcely be said to have explained gravitation, it has been widely held to have explained (or abolished) space and time: it merely forced gravitation, just as it happens to exist, into the electrodynamic frame with its property of insensibility to uniform convection, with no detriment to the results of Newtonian physical astronomy and a rather better account of the problem of the Mercury perihelion.

This empirical building up of a field of gravitation out of tensorial constructs belonging to a space-time expanse, now differentially heterogeneous, was completed by adapting the Minkowskian vector potential of the pervading electrodynamic and optical field to the same conditions. The need for a more physical setting, at any rate to those who believe in minimal Action as the ultimate and necessary binding principle in physical analysis of a molecular world, seems to have been met immediately to a considerable extent by Lorentz and soon after by Einstein himself and by Hilbert. "The discussion of some parts of Einstein's theory of gravitation may perhaps gain in simplicity and clearness, if we base it on a principle similar to that of Hamilton. . . . Now that we are in possession

of Einstein's theory we can easily find how this variation principle must be formulated for systems of different nature and also for the gravitation field itself" (Proc. Amsterdam Acad., Jan. 30, 1915). This is not the place to pursue the contentious view (cf. *Phil. Mag.*, Jan. 1923) that the Least-Action dress, just because it is so closely interwoven, is like the shirt of Nessus, and tends to make havoc of the spatial philosophy though without destroying the tentative validity of the elegant analytical method. Possibly Prof. Lorentz may be tempted to unravel this question in his admirable judicial manner.

In the subsequent years the Proceedings of the Amsterdam Academy became a focus for the literature of the gravitation theory, mainly in a series of papers, apparently first delivered as lectures, by Prof. Lorentz himself, in which he develops the tensor scheme in an elegant way of his own by a differential geometry involving use of infinitesimal loci of constant geodesic radius as a kind of indicatrix. Among many other papers, doubtless arising from a common inspiration, one recalls Droste's determination, simultaneous with Schwarzschild's solution, of the exact gravitational field of a particle, and Nordström's of the field of an electron.

One can look back, still with undiminished surprise, at the vast mass of intricate literature on this subject which flowed westward, mainly from Berlin and Leyden and Göttingen (and also from Italy), when Central Europe was again thrown open after the end of 1918. The difficulties of a strange though potent and elegant calculus could be surmounted by application; but the mysteries of unfamiliar meanings and implications in imaginary space and time could give rise to abundant misconceptions. The uninitiated must still be wary in approaching this unexplored and treacherous domain, in which Prof. Eddington has recently detected for us, by beautiful analysis of algebraic tensors, how mere co-ordinates are liable to undulate across the field on their own account entangled with the gravitational waves in the underlying spatial reality.

There is no space to pursue this review of Prof. Lorentz's work further. A survey of his activity is a liberal education in the history of physical science for the last half-century. Reference to the Proceedings of the Amsterdam Academy for the last twenty years, in the handsome form of the edition in English, will reveal the breadth and informative character of his investigations. But this series of volumes is long and portly; and he would confer a great boon on students of physical science the world over if he could manage to continue the edition of Collected Papers of which the first volume appeared in 1907. He will be excused the task of reconstruction to bring them up-to-date which he then essayed, and which perhaps has been a cause of the delay.

Needless to say, Prof. Lorentz has attained to all the distinctions all over the world that are appropriate for a man of science. He has long been a Foreign Member of the Royal Society, and is in the lists of Rumford and Copley medallists. For the working congresses on the theories of physical science that are a feature of our time, he is an almost indispensable chairman. Great linguistic gifts, abounding learning, clear and rapid grasp of a point of view and prompt exposition of it in a different language, ease of approach, tolerant appreciation and encouragement of speculations still unverified, are familiar to his scientific colleagues. We may hope that his time will not be diverted overmuch to administrative work such as could be done by others. JOSEPH LARMOR.

The Botanical Survey of British Malaya.

The Flora of the Malay Peninsula. By H. N. Ridley. Vol. 1: *Polypetalæ*. Pp. xxxv+918. (London: L. Reeve and Co., Ltd., 1922.) 63*s*. net.

THE Malay Peninsula, for which the opening volume of a Flora by Mr. H. N. Ridley has been published "under the authority of the Government of the Straits Settlements," is an important and, save for the narrow northern section nearest Siam, a typical province of the Tropical Rain-Forest Region. Though Europeans secured a footing in this Peninsula four centuries ago, the survey of its vegetation was long deferred. The Portuguese, who occupied Malacca in 1511, had done little before their expulsion by the Dutch in 1641. The Dutch, who, with two short breaks (1795–1801 and 1807–18), owned Malacca till 1825, scarcely did more. Rumpf, whose "Herbarium Amboinense" (1750), completed on September 20, 1690, surveys the vegetation of the Malay Archipelago, avoided dealing with Malacca. Rumpf regarded the Malay Peninsula as belonging to continental India, and Valentijn, in his "Oost-Indien" (1726), held the same view.

The British became interested in the Peninsula when Penang was acquired in 1786. Sir Joseph Banks, president of the Royal Society, satisfied the directors of the East India Company that a survey of the vegetable resources of their territories was essential, and in 1793 the Calcutta Botanic Garden was permitted to add survey operations to its acclimatisation work. The investigation of the vegetation of the Peninsula, then begun in Penang, was extended to Malacca when that Settlement was first captured from the Dutch in 1795, and to Singapore when that Settlement was

founded at the second restoration of Malacca to Holland in 1818. Before Malacca became permanently British in 1825, Banks had died and the company had adopted another policy. Botanical survey at Calcutta was inhibited, and during 1828–32 the company dispersed the contents of the Calcutta Herbarium.

The valuable work accomplished by the Calcutta Garden since 1793 in Penang and Singapore, however, could not be undone; as regards Malacca, the reproach to England induced by this retrograde policy was removed by the private exertions of Griffith during 1841–44 and Maingay during 1862–69, whose collections went to Kew. Largely owing to Griffith's work, more than one-sixth of the plants described by Hooker and Thomson in their "Flora Indica" (1855) are Straits Settlements species; thanks to Maingay, the Straits Settlements plants in the two opening volumes of Hooker's "Flora of British India" (1872–79) rose to nearly one-fourth of the whole. During 1874–79, the Straits Government organised relationships with the western Native States which rendered the latter accessible. To assist Hooker the Calcutta Garden undertook, during 1881–86, the botanical investigation of Pêrak, and the Malay Peninsula plants described in those parts of Hooker's Flora issued during 1887–97 rose to nearly one-third of the whole.

In 1888 Mr. Ridley was appointed Director of Gardens and Forests, Straits Settlements; in 1889 King, at the desire of Kew and of the Straits Government, began at Calcutta his "Materials for a Flora of the Malayan Peninsula," as a supplement to the Indian Flora Hooker had already issued and a precursor of the Malay Flora Mr. Ridley has now commenced. By 1902 King had completed the Polypetalæ; the Materials of 1889–1902 thus correspond with the 1872–79 parts of Hooker's Indian work and with the first (1922) volume of Ridley's Malay flora. Two-fifths of the plants in King's Materials had not been reported from the Peninsula when Hooker's work was written; one-third were new species. Nearly one-fourth of the plants now described by Mr. Ridley had not been reported from the Peninsula when King wrote; one-seventh are species discovered since the Materials appeared. The vegetation of the Peninsula in wealth and variety claims comparison with the richest province of the Tropical Rain-Forest Region.

If much has been done to remove what was long a reproach to Europe, much, as Mr. Ridley explains in his introduction, has still to be accomplished before the vegetation of the Malay Peninsula can be regarded as fully investigated. A generation hence the additions to his Flora may be as extensive as his additions to King's Materials. This only increases our obligation to him for placing at the disposal of economic students the ripe and exact knowledge of which he has such a store, and gives rise to the hope that he may soon complete the task so worthily begun. His descriptions are clear and concise, and he has done well to confine his citations of earlier authorities within rigid limits; if there be a fault, it lies in the fact that occasionally he has exceeded his own limits by omitting references to the works he usually cites. By adding text-figures illustrating most of the families discussed, he has enhanced the value of the work; Mr. Hutchinson's drawings are so effective that the only regret they cause is that they should be so few. Those who use the work will not confine their commendation to the author and his artist; if the price be considerable, it will at least be conceded that printer and publisher alike have fulfilled their duties well.

Geodetic Levelling.

Ordnance Survey: The Second Geodetic Levelling of England and Wales, 1912–1921. Published, by Order of the Ministry of Agriculture and Fisheries, by Col. Sir Charles Close, Director-General of the Ordnance Survey, Southampton, 1921. Pp. 62+46 plates. (London: H.M. Stationery Office, 1922.) 17*s.* 6*d.* net.

THE accuracy of modern levelling is a thing which always causes surprise when the great number of separate operations which enter into the composition of a line of any length is considered.

In the work under notice perhaps the most striking result is that the line of levelling starting from mean sea level at Newlyn, not far from Land's End, and terminating at Dunbar on the coast of Haddingtonshire, generates in all that distance of about 600 miles a probable error of only two inches, so that, when it was found that mean sea level at Dunbar was ten inches above that at Newlyn, it was possible to say with confidence that the discrepancy was real and due to a deformation of the mean sea-level surface and could not be attributed to an accumulation of error in the levelling.

The volume contains an introduction by Colonel Sir Charles Close, four chapters by Lt.-Col. A. J. Wolff, and five by Mr. H. L. P. Jolly. The operations which it describes fall into two separate parts, namely, the determination of the mean sea level and the levelling.

Though the old levelling of England had mean sea level at Liverpool as its datum, the height of mean sea level had not been determined with accuracy, and a new determination was necessary; it was very desirable also to obtain records whereby the fluctuations of mean sea level could be examined and analysed. Accordingly, three tidal observatories with automatic

gauges were established, at Newlyn, Felixstowe, and Dunbar respectively. In the selection of these places the late Sir George Darwin was consulted.

The levelling shows that the equipotential surface through the mean level of the sea at Newlyn passes well below mean sea level at Dunbar and slightly above that at Felixstowe. There is thus a question as to what should be adopted as the datum for the levelling. Either the mean of the different sea levels might have been used or the equipotential through mean sea level at one point might be the datum for all. The latter was decided on and the decision was unquestionably right.

An interesting chapter is devoted to the effect of meteorological conditions on the level of the sea. This shows that part of the discrepancy of 0·81 ft. between mean sea level at Newlyn and Dunbar can safely be attributed to the fact that, for the six years during which the observations continued, the average barometric pressure was higher at Newlyn than at Dunbar by 0·108 in.; this would depress the level of the sea at Newlyn by about 0·12 ft. The greater portion of the difference still remains to be accounted for, however, and it seems that the cause may best be sought in the effect of wind.

The relation between the daily mean level of the sea at Newlyn and the atmospheric pressure-gradient has been studied and a formula deduced that gives results in wonderfully good accordance with observation.

That the levelling was carried out with conspicuous care and success is demonstrated by the smallness of the probable error of the long line from Newlyn to Dunbar; and the heights of the bench-marks are now known with such accuracy that if in the future these are found to have changed it will undoubtedly indicate that the marks have moved. The old levelling of 1850 was unfortunately not precise enough to permit of the differences found, considerable though they were, being attributed to real movement.

Particular attention has been paid to the design and to the selection of the situations of the bench-marks, on the stability of which the value of the work depends. The sites have been chosen with special regard to the geological conditions, "avoiding as far as possible the softer rocks and those liable to surface changes."

In the design of the primary bench-marks an interesting detail is that two reference marks, situated side by side, are provided in each; one is a piece of gun-metal and the other a polished flint. The number of primary bench-marks is large, the interval between them being on the average about thirty-five miles, and it is scarcely possible that any upheaval or subsidence of a geodetic kind can take place without affecting the heights of some of them.

The discussion in Chapter IV. of the dynamic and orthometric connexions is clear and good, but it should perhaps have been stated, with reference to the formula for the value of gravity, that though in all probability the results obtained by the use of Helmert's constants are sufficiently accurate, yet the correct quantity to employ is not the computed value of gravity but the actual value obtained by observation. We may feel tolerably sure, from experience gained in other countries, that the difference between these two values will not be great, but as no gravity survey of this country has ever been made we cannot say that we *know* that that is the case.

The errors to which levelling is liable are fully discussed in Chapter VIII. The origin of the systematic errors, which are undoubtedly met with, is obscure. It is here stated that "the systematic error must be systematic with respect to something and there is always the possibility of finding out what the determining condition or thing is. It is a matter of almost universal experience that the direction of levelling is one such condition." Until, however, some satisfactory explanation has been given of the way in which the direction affects the errors it cannot be said that the connexion has been definitely established.

The French levellers, under the direction of M. Ch. Lallemand, have probably paid more attention to this question than any one else, and it is worth noticing that the early procedure was to do the levelling in both directions on the same day, whereas now the rule is to do the second levelling on a different day. If the systematic error were principally due to the direction the best procedure would clearly be to do the two levellings on the same day, under as similar conditions as possible, when the effects of direction on the two results could be expected to be equal but opposite. It seems that this was the original expectation; experience, however, showed that the expectation was not fulfilled, and so the preference was given to separate dates, "qui assure" (to quote M. Lallemand) "une plus grande variété dans les conditions atmosphériques d'exécution des deux nivellements et, par suite, en cas de concordance de ceux-ci, autorise davantage à penser qu'ils sont exempts d'erreurs systématiques."

This evidence, however, is not very conclusive. Concordance may merely indicate that the errors were equal and of the same sign in both cases, so that whatever error there was will appear undiminished in the mean. Discordance means that most probably the errors were of opposite sign, but, the conditions under which the two levellings were done having been different, it would be unjustifiable to assume that the errors were equal. In neither case, therefore, have we any certainty that the mean of the two results will be free from error.

We agree with the statement made in Chapter VIII. " that there is reason to doubt whether the systematic error in the mean levelling of a line, derived from the discrepancy between the backward and forward levelling, is a reliable guide to the actual accumulation of error within the line."

Putting aside such matters as instability of pickets, which are clearly capable of producing a systematic effect depending on the direction in which the work proceeds, the connexion between the remainder of the systematic error and the direction does not seem to be well established and is a matter which calls for further investigation.

Turning to the equipment which was used for the levelling, special attention is due to the staves called the " Cambridge Staves," which came into general use in 1914. They are described by Lt.-Col. Wolff in Chapter II. The novelty of their construction is that the graduations are not on the wood of which the body of the staff is composed, but on a strip of invar let into a groove on the face of the staff. This strip is firmly attached to the base of the staff, and is presumably kept taut by some arrangement fixed at the top, but this detail of the construction is not given.

The thermal expansion of invar is so small that no account has to be taken of changes of temperature, which simplifies the computations and adds to the precision of the work. Staves of this pattern would be still more advantageous in countries where the climate is less temperate than it is in England.

The book is well illustrated, and the closing errors, discrepancies, adjustments, and route-profiles of the circuits are very clearly displayed in a series of diagrams. The work is well produced on the whole, but there are signs that the printers were not quite accustomed to mathematical symbols with accents, subscripts, etc. These are minor blemishes, however, and do not detract from the great value of this admirable piece of work. G. P. L. C.

Scientific Work in the Dutch East Indian Seas.

De Zeeën van Nederlandsch Oost-Indië. Uitgegeven door het Koninklijk Nederlandsch Aardrijkskundig Genootschap. Pp. ix + 507. (Leyden : E. J. Brill, 1922.) 20 guilders net.

THIS heavy volume, illustrated with numerous photographs and several folding maps, treating of our knowledge of the Dutch East Indian seas, is published by the " Koninklijk Nederlandsch Aardrijkskundig Genootschap " on the occasion of its fiftieth anniversary. In it, six specialists give a summary of the work done in their respective branches of science, and the results are worthy of the attention of many more than those acquainted with the Dutch language.

In the first chapter, Col. l'Honoré Naber gives a historical sketch of the research work that has been done, beginning with the famous Marco Polo, the first European who travelled in those seas in the thirteenth century, and whose book was translated into English by H. Yule (London, Cordier, 1903). More important for us, however, are the expeditions of the last century, when the *Challenger* began the work which was carried on by the *Siboga* and the *Bali*.

The second chapter, bringing forward Adm. Tydeman's work on the depths of the sea, is accompanied by a splendid map, showing the extension of the flats, as well as the distribution of the curious deep channels or troughs, that form one of the most characteristic features of this part of the world ; for example, the Java trough, 6000-7000 metres deep, the Mentawei trough, and the well-known Mindanao trough, where the greatest depth of the sea, between nine and ten thousand metres, is found.

Then follow accounts of investigations on temperature, salinity, density, and dissolved gases in the sea water, communicated by Prof. Ringer. Many diagrams and tables are a welcome guide in what might have been a labyrinth of ciphers.

An account of the maritime meteorology and the tides, written by Dr. van der Stok, and illustrated by maps and tables, explains the interesting phenomena which tide-waves show in an archipelago, the isles of which form numerous obstacles to the movements of the water. The theoretical part of this chapter is highly interesting.

Dr. Max Weber's treatise on the biology of the sea is very important, as might be expected from the leader of the *Siboga* expedition. The different zones of life in the oceans, the coral reefs, and the conditions of deep-sea life are especially treated, and Mrs. Weber-Bosse adds an important chapter on plant life in tropical seas, which is so absolutely different from our coastal vegetation, where only very few Phanerogamæ come down to and into the salt or even brackish water of bays and estuaries.

The next chapter, on the geology of the region, by Prof. Molengraaff, is perhaps the most interesting of the volume. The writer first points out the remarkable difference between the western and eastern parts of the Archipelago. The western part, the shallow Soenda sea, was dry land during the Glacial period, while in the eastern part rows of little islands alternate with deep-sea basins, causing a very unequal relief of the sea bottom. The theory of the sinking of the sea-level and the coral-reef problem, which are narrowly

interlaced, are amply discussed. Good maps help to make these difficult problems easier to understand.

In the last chapter Adm. Phaff gives a description of the coast lines of the East Indian Isles.

In his preface Dr. W. v. d. Stok states that only new and very costly expeditions will be able to bring new light on the subjects treated in this volume, so we must therefore be glad to possess such an excellent summary of our knowledge of the East Indian Seas.

W. G. N. VAN DER SLEEN.

For the Diffusion of Knowledge.

Annual Report of the Board of Regents of the Smithsonian Institution, showing the Operations, Expenditures, and Condition of the Institution for the Year ending June 30, 1920. (Washington: Government Printing Office, 1922.)

OF the 704 pages that make up the volume before us, 550, accompanied by 230 plates, are assigned to the appendix. The body of the report is somewhat dead by now, but the large tail is still lively enough to attract attention. It consists, as usual, of papers general in character and ranging over the field of human intellect from astronomy to fine art. There are 27 such papers, of which 14 are original and by Americans, and 13 are reprints or translations of articles by American, British, and French authors. All are examples of popularisation of a high type, and many of them could be understood by readers with little or no previous knowledge of the subject. The names of H. H. Turner, W. D. Halliburton, M. Caullery, and Auguste Lameere among the foreign authors indicate the general excellence. The papers that appear here for the first time are, to a large extent, summaries of work that has been published elsewhere, but some of them contain matter that seems to be fresh.

Dr. N. E. McIndoo's article on the senses of insects may serve for example. After discussing the nature of insect vision by the simple and the compound eyes, he proceeds to the sense of smell, and considers it first as a means of recognition. In insects that sense is far more developed than in man, yet Dr. McIndoo found that by smell alone he could distinguish the three castes of bees as well as other components of the hive. It is probable that each individual bee has its peculiar odour, but the combination of all these that makes up the hive odour is regarded as the most important, as indeed the ruling power in a colony. It "is a means of preserving the social life of the bees from without, and the queen odour which is a part of it insures continuation of the social life within. The workers 'know' their hive-mates by the odour they carry. This insures harmony and a united defence against attack. The queen odour constantly informs the workers that their queen is present. Even though she does not rule, her presence means everything to the bees in perpetuating the colony. Thus, by obeying the stimuli of the hive odour and queen odour, and being guided by instinct, a colony of bees perhaps could not want a better ruler." Among ants the same broad principles hold, but here the family odour retains its importance.

What then are the organs by which insects recognise these odours? Dr. McIndoo has identified them as small pores scattered or grouped on the body and appendages. A nerve ends in each pore, and the opening is often protected by a hair. By covering the pores, experimental proof of their olfactory function was obtained.

That bees, among other insects, can discriminate between foods is well known, and that their power of discrimination exceeds that of man was experimentally proved by Dr. McIndoo. He ascribes this power, however, not to taste, but to smell. Taste and smell are closely allied, and it is possible that the only difference lies in the organs that respond, the stimulus itself being identical. In bees there appear to be no such organs connected with the alimentary tract, so that the discrimination is probably by smell.

Passing over the sense of touch, we find some novel remarks on the sense of hearing, and an interpretation of certain organs on the antennæ (pore-plates and Johnston's organ) as possibly auditory in function, though the audition can, in that event, be little more than an exaggerated sense of touch.

Whether there are in insects or in any other animals senses of a nature entirely hidden from us, is a question raised by Mr. H. H. Beck in an article on "The Occult Senses in Birds" (reprinted from the *Auk*). In some species of moth, for instance, a female exposed but invisible will soon attract the males of the species. Various explanations of this have been suggested—from Mr. Beck's "mate-finding sense" to wireless telegraphy, but Dr. McIndoo believes that the highly developed sense of smell is enough to account for it. The same faculty surely renders it unnecessary to postulate, with Mr. Beck, a special "food-finding sense," though his story of vultures from eight miles away spotting a freshly-killed dog at the bottom of a sink-hole is certainly uncanny. Then there is the homing sense—the most puzzling of all; but it seems less rational to demand some mysterious force, as Bethe does, than to suppose the exercise of the usual senses more highly developed than a townsman can ever imagine, used simply or in combination, consciously or unconsciously.

One might pass on to consider some curious instincts

set forth in the account of two insects of the orchard, by Mr. R. E. Snodgrass, or to learn a lesson from Prof. Lameere's lecture on the origin of insect societies. Or one might get practical hints on the suppression of insect pests by a better utilisation of birds from Mr. W. L. McAtee, or excite oneself over the adventures in the life of a fiddler crab, so delightfully told by Mr. O. W. Hyman. But we must reluctantly pass all these, and pass too Mr. Bassler on the little Polyzoa, Mr. Gilmore on the mighty horned dinosaurs, Mr. Maxon on the Botanical Gardens of Jamaica, Mr. Safford's strange study of the narcotic Daturas, and the richly illustrated articles on Hopi Indians, modern Mexicans, and racial groups and figures, by Fewkes, Genin, and Hough. We must end, but we permit ourselves the perhaps too obvious comment, that this publication is indeed an admirable example of "the diffusion of knowledge among men."

Our Bookshelf.

Introduction à la géométrie non-Euclidienne. Par Dr. A. MacLeod. Pp. 433. (Paris: J. Hermann, 1922.) 20 francs.

IN the theory of relativity, on which so much has been written during the last few years, one of the main difficulties encountered by most readers is the unfamiliar conception of space and time involved. Apart from the difficulty in the conception of a space-time continuum, the notions that space as we know it may possibly be only of limited extent, and that the sum of the angles of a triangle is not necessarily equal to two right angles, are apt to prove only too bewildering to readers whose knowledge of geometrical matters is confined to the Euclidean system.

The question whether the axioms imposed by Euclid are necessary for building up a logical system of geometry has long engaged the attention of mathematicians. In the non-Euclidean system, largely developed by Gauss, the absolute, *i.e.* the "circular points at infinity" of Euclidean geometry, is replaced by a non-degenerate conic. All this entails revised definitions of such terms as "distance" and "right angle."

Dr. MacLeod in the work before us presents the subject with strict logical precision, the reasoning which leads to the various results being given fully and accurately. The actual amount of ground covered is not so great as in Mr. Coolidge's treatise, a book which occasionally suffers from over-condensation. Uninitiated readers will be interested in noticing that the proof of a familiar proposition, that the greater angle of a triangle is opposite the greater side, requires six pages of reasoning. The book would have been improved by more diagrams, but these can be supplied without difficulty. It can be recommended as an excellent introduction to the subject.

W. E. H. B.

History of the Theory of Numbers. By Prof. L. E. Dickson. Volume II. (Publication No. 256, Vol. II.). Pp. xxvi + 803. (Washington: Carnegie Institution of Washington, 1920.) 7.50 dollars.

THE arithmetical questions treated by Diophantus of Alexandria, who flourished about the year 250 A.D., included such problems as the solution of the equations

$$x+y+z=6, \quad xy+z=u^2, \quad xy-z=v^2$$

in rational numbers. Little attention was given to this type of problem from Diophantus's time till that of Fermat (1650), the founder of modern Diophantine analysis. The most general arithmetical question to which the peculiar methods of Diophantine analysis apply is the determination of all the solutions in rational numbers of a system of algebraic equations.

$$R_i(x_1, x_2, \ldots x_n)=0, \quad i=1, 2, \ldots m,$$

there being more unknowns than equations. Particular problems of this type have attracted the attention of a very large number of workers.

Prof. Dickson, in the second volume of his History, gives an account of what has been accomplished in this field of thought. Original memoirs have been carefully scrutinised and abstracted. Naturally, in such a compilation, there is much matter which would not now be regarded as of any great scientific importance, and, in fact, the main value of many of the reports is on the side of historical development.

Scientifically, the most important chapters in the present volume are those on (i.) partitions of numbers, (ii.) representation of numbers as sums of squares, (iii.) Pellian equations, (iv.) indeterminate equations of the third degree, and (v.) Fermat's last theorem. It is to be trusted that the mathematical world will duly appreciate the immense amount of labour expended by Prof. Dickson in the preparation of such a book.

W. E. H. B.

Penrose's Annual: The Process Year Book. Review of the Graphic Arts. Edited by William Gamble. Vol. 25. Pp. xvi + 110 + plates + 64. (London: Percy Lund, Humphries and Co., Ltd., 1923.) 8s. net.

MR. GAMBLE, in his editorial review of process work, looks back twenty-seven years to the first volume of this annual and remarks upon the improvement of the process block since then. He considers that it is now so perfect that there is little if any possibility of advance in this direction. "The signs of the times are that the process block has passed its prime and that there will be a slow and steady diminution of its employment." Rotary photogravure and off-set lithography are improving, and collotype is reviving, its most important application being in the highest grade of colour work.

The superseding of type composition by a photographic method occupies a prominent position in the volume. The "photoline process" of Mr. Arthur Dutton, though the machinery for it is not yet on the market, is so far perfected that we have here good examples of solid text, tabular matter, title pages, ornamental work, and a demonstration that any size of letter can be obtained from one master alphabet.

The body of the book contains several articles of exceptional value following the editor's general summary. Mr. Stanley Morison contributes a long and well illustrated historical article on "Printing in France," and "Printing in China" is dealt with in a

shorter contribution by Mr. Gilbert McIntosh. There is also a note on the Garamond Type, with several examples of it. The illustrations representing process work are, as usual, numerous and very diverse. They include a reproduction from an impression of a wood engraving by the swelled gelatine method and a half-tone direct from Nature. Altogether it is a very interesting volume.

The Psychology of Thought and Feeling: A Conservative Interpretation of Results in Modern Psychology. By Dr. C. Platt. Pp. x+290. (London: Kegan Paul, Trench, Trubner and Co., Ltd., 1921.) 7*s.* 6*d.* net.

THE author's claim in the sub-title is, on the whole, justified. The social and educational bearings of the subject are kept in the foreground; technicalities and controversial or metaphysical problems are, for the most part, avoided. On these terms, as stated in the preface, one is not led to expect more than one finds—a presentation that includes much of the newer teaching but does not break touch with older methods of treatment. The trouble, perhaps, is that if "metaphysical" problems be avoided the result is likely to be an emulsion in which the drops do not combine though they may be swallowed together. If we elect to follow M. Bergson and call the great life-urge the *élan vital*, the concept of nerve-force or neurokyme and that of unconscious cerebration can scarcely coalesce therewith; and if the nerve-force be said to leap a microscopic gap at the synapse, and if it be also said that at each of these gaps, a choice presents itself, the two statements do not seem to be "metaphysically" *in pari materia*. The author is doubtless not less aware than any of his readers of the difficulties that must arise if the more fundamental issues be passed over. For the most part he gives a reading of the facts which will be found sufficiently free from extravagance as to be spoken of as conservative.

Researches on Cellulose. By C. F. Cross and C. Dorée. IV. (1910–1921). (Vol. 4 of the Series "Cross and Bevan.") Pp. x+253. (London: Longmans, Green and Co., 1922.) 15*s.* net.

"CROSS AND BEVAN" are two names inseparably connected with our knowledge of cellulose. The present volume is a continuation of a series of monographs on the subject. Although the properties of cellulose are of such immense importance in nearly all branches of industry, the complexity of the subject is so great that, in spite of a considerable volume of valuable research, there are still many obscure regions. The authors have brought together the results of research carried out by various workers, with helpful and constructive criticism. The result is a very useful monograph, which will be of great value to workers in this field.

The Psychology of Day-Dreams. By Dr. J. Varendonck. With an Introduction by Prof. S. Freud. Pp. 367. (London: George Allen and Unwin, Ltd.; New York: The Macmillan Company, 1921.) 18*s.* net.

THERE is much in Dr. Varendonck's book which will be of interest and of value to psychologists not only of the newer schools but also to those who are nowadays spoken of as "academic." The central aim is to disentangle under distinguishing analysis the part (1) played by "affective thinking" (or what Prof. Freud in the introduction prefers to call "freely wandering or phantastic thinking") in normal life, from (2) that which is played by psychical processes in which a higher order of reflective thinking takes some share. To this end, day-dreams are discussed with much patience and insight. The conclusion reached is that affective thinking may take place in the three levels of consciousness, but that unconscious and fore-conscious thinking are always affective. Where so much turns on the rôle of the affect, chapters on its relation to memory, apperception, ideation, and visualisation, and one on the issues of affective thinking, are helpful to an adequate grasp of the author's position.

The Common Molluscs of South India. By J. Hornell, Director of Fisheries, Madras. Report No. 6 of 1921, Madras Fisheries Bulletin, vol. xiv., 1922, pp. 97-215. (Madras: Government Press.) 1 rupee.

MR. HORNELL has arranged for the preparation of wall-cases containing collections of the common species of molluscs and crustacea for the use of secondary schools in India, and this useful handbook was written primarily as a descriptive guide to accompany the case of molluscs, but the needs of collectors who take an interest in the things they find on the shore have also been kept in mind. Mr. Hornell records the external features, the bionomics, the changes in form of the shell as growth proceeds, the character of the spawn, the use of molluscs as food, and the shells, opercula, pearls, etc., as articles of commerce.

The Evolution of Atoms and Isotopes. By W. D. Verschoyle. Pp. 40. (London: J. J. Keliher and Co., Ltd., Craven House, Kingsway, 1922.) 1*s.* 9*d.*

THE author of this pamphlet proposes, with the help of a bi-polar electron, to explain the evolution of atoms and to abolish positive electricity. He has been stimulated by the discovery of isotopes to develop further a series of numerical relations between atomic weights, some of which have already been described in the *Chemical News*.

An Introduction to Forecasting Weather. By P. R. Zealley. Pp. 32. (W. Heffer & Sons, Ltd., Cambridge; London: Simpkin, Marshall & Co., Ltd., 1922.) 1*s.* net.

THE pamphlet treats the subject of forecasting in an elementary manner, and may interest amateur meteorologists who have receiving sets for radio-telegraphy. The author is a technical assistant in the Meteorological Office stationed at Shoeburyness, and would be conversant with the official weather publications.

Ministry of Munitions and Department of Scientific and Industrial Research. Technical Records of Explosives Supply, 1915–1918. No. 9: *Heat Transmission.* Pp. iv+48. (London: H.M. Stationery Office, 1922.) 5*s.* net.

THIS report embodies in charts and formulæ the experiences of the Department of Explosives Supply on the transmission of heat to or from fluids flowing along pipes under various conditions, and will be found useful by engineers.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Broadcasting Transmitter.

I EXPECT that broadcasters would find that a definite generator of E.M.F. would give cleaner articulation than is probable with a transmitter depending on random variation of resistance. In other words that one of those telegraphic devices which I described long ago (Proc. Inst. E.E., vol. 27, p. 838, Dec. 1898), consisting of a light stiff coil of fine wire suspended elastically in an annular magnetic field, would reproduce speech and music better than a microphone. The fluctuations of the induced current in such an instrument are not capricious, and apart from stimulation it is silent; always provided that the exciting magnetic field is kept steady—a condition likely to be assisted by saturation of the iron magnet core, or by use of a sufficiently strong permanent magnet.

If an electromagnet is used, some contrivance is advisable whereby the coil circuit is automatically opened whenever the rousing current is put on or off. Otherwise, the response may be too violent for the valve and rest of the apparatus, not to mention a receiving ear. OLIVER LODGE.

Normanton House, Lake, Salisbury.

The Green Flash at Sunset.

SIR ARTHUR SCHUSTER in his review of Dr. Mulder's book on this subject states that "there seems no reason to doubt that dispersion combined with absorption of light completely accounts for the effect" (NATURE, September 16, p. 370). Yet Dr. Mulder's own view is that a complete explanation is still wanting.

My apology for again raising this question is that I believe I can supply from some recent observations what seems to be lacking in the dispersion theory, which fails to account for the remarkable variations in visibility of the green flash under apparently favourable conditions.

On the outward voyage to Australia to observe the solar eclipse of September last, I was struck with the faintness of the green flash at sunset, although the sky was clear down to the horizon. It was visible in binoculars (×8), but scarcely, if at all, to unaided vision. On the return journey, on the other hand, the phenomenon was brilliant every evening on the run between the north-west coast of Australia and Java, and I was able to observe also what happened when Venus set in the sea. On this voyage the ordinary mirage effect was conspicuous, that is, distant land appeared raised above the sea horizon by a small interval, due to the total reflection of sky and land at the surface of a thin layer of air of low density in contact with the sea. At sunset the last segment of the disappearing limb was similarly reflected and reversed, causing a lenticular shape with the cusps raised about a minute of arc above the horizon. The green flash occurred when the green-edged cusps coalesced into a single bright patch, and this on one occasion turned to violet at the last moment.

The striking thing about the setting of Venus was the sudden appearance of a reflected image moving upwards to meet the descending image, and the instantaneous and conspicuous change of colour from dull red to green at the moment of meeting of the two images. The vertical spectrum of the planet caused by atmospheric dispersion was at no time visible in the binoculars, but the change of colour was probably due to the setting of the lower red of the spectrum.

It seems to me evident from these observations that the mirage layer greatly intensifies the ordinary dispersion effect, by adding the light from the reflected image to the direct image at the moment of setting. The normal dispersion effect at sunset under conditions when there is no mirage is scarcely visible to unaided vision, although easily seen in a telescope of low power. J. EVERSHED.

Kodaikanal Observatory, September 26.

Thermal Opalescence in Crystals and the Colour of Ice in Glaciers.

IN a previous communication to NATURE (vol. 109, page 42) it was pointed out that the thermal agitation of the atoms in crystals causes optical heterogeneity which should give rise to a noticeable scattering when a beam of light is sent through the substance, and that this effect may actually be observed with suitable arrangements in clear quartz or rock-salt. I have recently found that the same phenomenon is conspicuously exhibited by ice. If a block of clear ice, free from air-bubbles, striæ, or other obvious inclusions, and having flat sides, be held squarely and a narrow pencil of sunlight concentrated by a lens be passed through it, the track of the pencil shows a beautiful blue opalescence. It is advisable not to use a very highly-condensed cone of rays, as this would cause internal melting of the ice with formation of cavities which reflect white light and distract the eye. A dark background should be provided against which the track may be viewed. With small or irregular lumps of ice, the observation may easily be made by immersing the ice in clear distilled water contained in a glass flask which is painted black outside, windows being provided for ingress and egress of light and for observation of the opalescent track. Even with ice which at first looks unpromising owing to internal flaws or inclusions, portions in which the blue opalescence is not overpowered by disturbing effects may be picked out. A suitable orientation of the block with reference to the direction of the incident rays is often useful in avoiding reflections from cavities in the ice.

A comparison of the relative scattering powers of clear water and of ice at 0° C. is instructive. According to the measurements of Bridgeman, the compressibility of ice is 35×10^{-6} per atmosphere, and its refractive index is 1·310, while the corresponding figures for water are 52×10^{-6} per atm., and 1·334. The Einstein-Smoluchowski formula gives the scattering power of water at 0° C. as 144 times that of dust-free air, and if it could be applied in the case of solids, the scattering power of ice should be 79 times that of air. As has already been pointed out, however, the formula has to be modified in the case of crystalline solids, and a revised calculation indicates the scattering power of ice as about 30 times that of air, which is of the order actually observed in experiment.

The atomic scattering of light in block-ice demonstrated and measured in these experiments should certainly be capable of being observed on a large scale under suitable natural conditions. Indeed, it is well known that masses of ice in glaciers and icebergs often exhibit a blue colour, and it appears to the writer very significant that the circumstances in which natural ice shows a blue colour are precisely those found to be

necessary in the laboratory in order that the blue opalescence due to internal scattering may be satisfactorily observed, that is, that the ice should be of the maximum clearness and transparency; in either case, air-bubbles, striæ, and other inclusions obscure the effect sought for. The inference that the phenomena arise in the same way seems legitimate.

I am aware that a different explanation of the colour of natural ice has been put forward by Tyndall and other writers, that is, that the colour is simply an absorption effect. To me, however, it appears that the latter view presents fundamental difficulties. *Prima facie*, no substance can exhibit colour *in its own body* except as the result of internal diffusion or scattering. Colour due to simple absorption can only be perceived when a luminous object is viewed through the substance, and even then it is the source, not the absorbing medium, that appears coloured.

The absorption theory thus leaves it unexplained why clear ice should exhibit any colour at all. Indeed, it would appear that the colour of ice is often very conspicuously observed when the light traversing it has no chance of reaching the observer's eye directly. Thus, for example, in his lecture on ice and glaciers, Helmholtz describes very vividly the experience of the Alpine traveller who, traversing the broken surface of the glacier along a narrow ridge, looks down into the crevasses on either side and views with mixed feelings of pleasure and awe their dark blue walls going down to the depths. It is obvious that in such a case as this, the light filtering *down* into the solid mass of transparent ice forming the glacier through the superficial layers or otherwise, has no possibility of returning to the observer above except as the result of internal scattering.

The natural view to take is therefore that the blue opalescence is the real cause of the colour of transparent ice observed under such conditions, the absorption of light in traversing the medium tending merely to diminish its intensity and make it of a more saturated hue.

The Cause of Chambering in Oysters and other Lamellibranchs.

THE phenomenon of chambering in oysters and other lamellibranchs is well known, and in oysters is a source of much financial loss to some oyster planters. In a chambered oyster one extensive closed chamber or several superposed large chambers may occur enclosed within the shell substance—usually in the convex valve, but sometimes in both valves. The chambers are separated from each other or from the body of the oyster by thin brittle partitions of shell only, and contain usually an evil-smelling liquid. When a chambered oyster is opened, great care is required lest the brittle wall of the chamber be broken and the evil-smelling liquid released on the oyster, which would in that case be rendered unfit for eating.

The cause of chambering has recently been described by Houlbert and Galaine (*Comptes rendus*, Acad. Sci. Paris 162, 1916), not as "un accident pathologique . . ." but "comme la persistence d'une propriété ancestrale." Later, these writers suggest inanition as a cause. In our recent investigation on oysters we have observed several phenomena which when pieced together offer a rational explanation of chambering as a minor pathological phenomenon due to varying external conditions coincident with variations in the internal condition of oysters.

We have observed that when oysters are kept in bell-jars or dishes in a warm room in the laboratory without food in winter they begin to grow shell automatically, whereas in the sea in a normal winter no growth of shell occurs; moreover, oysters kept in the laboratory in summer may continue to lay down shell at a rapid rate although food is practically absent. In such oysters it frequently happens that owing to the unfavourable conditions of transport in summer weather the oysters arrive in a bad condition, one of the effects of which—combined with the effect of the laboratory water—is to cause the oysters to shrink somewhat in their shell, but especially to contract the mantle, whereby puckers are formed in it. Now, although the mantle and body shrink, the layer of the mantle and body next to the shell continues to secrete shell substance in a thin layer. As a consequence of these conditions the oysters lay down on the inside of the shell a thin layer of shell-substance in an irregular manner, following especially the puckerings of the mantle. This thin layer of shell is laid down with a water space between it and the shell, and is, in fact, a small chamber. The same process occurs, as is well known, when mud gets into the shell accidentally, or when a hole is punctured in the shell and is afterwards plastered over with repair shell inside. The above facts show that shell is laid down automatically by the mantle and body surface adjacent to the shell if the temperature is sufficiently high and—it may be added—if the oyster is in reasonably good condition.

The second observation is well known to oyster-cultivators, namely, that oysters will swell considerably in water of low salinity and shrink in water of high salinity. This change occurs probably through the readiness of the bladder-tissue in lamellibranchs to respond and accommodate itself to changes in osmotic pressure. Now, chambered oysters occur most commonly on beds in high estuarine or riverine situations, where the salinity variations are great. The third factor of interest in this problem is that oysters vary greatly seasonally in weight, and, it can be safely deduced, in volume as well: very low salinities due to heavy rains would certainly also reduce the amount of available food-material for oysters. We have also observed that when oysters are kept for some months in tanks in stagnant water, the salinity of which thereby increases considerably, the percentage of chambered oysters is afterwards found to be very high and the bodies of the oysters shrink to a very great extent. The last factor of importance is this, that the rainy period in England falls either in the early part of the year or at the end of the year, while the month of May is fairly dry; but in May and June oysters prepare or begin to breed, and it becomes warm enough normally for shell to grow.

These observations may now be pieced together. In the early months of the year in high estuarine or riverine beds oysters are frequently subject to low salinities, *e.g.* 15 per cent. or even lower; towards May or June higher salinities will generally occur in these situations together with the onset of breeding among oysters; both these factors tend to reduce the volume of the body of the oyster, and—it has been noted—at a time when it is warm enough for shell-growth to take place. If the oyster is in good condition, shell-growth—it has been observed—occurs automatically. Thus, as the volume of the oyster is shrinking in these situations, shell material is being produced, consequently a shell lamina which is not adjacent to the existing body of the shell is laid down and a chamber results. Water probably forms in the chamber by percolation along the outside of the body of the oyster between the body and the shell. In this way are probably included in the chamber

various organisms—present in the sea-water—which give rise to the unpleasant smell. The principal organisms concerned would appear to be the well-known anaerobic bacteria which produce hydrogen sulphide.

The cause of chambering among oysters on beds in high estuarine situations can therefore be stated to be the reduction in bulk of the body, which occurs at the shell-growing period in these situations from a variety of causes, of which the decrease of bulk due to breeding and salinity variations are the most important.

It may be noted, however, that chambering is rare on what are regarded as good oyster beds, and there is good reason to believe that the salinity variations over such beds range between about 30 and 34 per mille.

Chambering has also been observed in some deep-sea oysters, and, it may be presumed, from the operations of the same causes as in high estuarine situations. The conditions on deep-sea oyster beds are very different from those in high estuarine situations, but the breeding phenomena on the former beds are not known. It seems probable that breeding may not occur at all in some years in deep-sea beds, or that there is only a short breeding period (see Orton, Journ. Mar. Biol. Assn. vol. 12, p. 343), but that on the other hand growth is probably continuous over the greater part of the year. Since salinity variations would not be great on deep-sea beds it would appear that the reduction in bulk of the body due to breeding coincident with extensive shell-growth (see Hoek, Report on the Causes of the Deterioration in Quality of the Zealand Oyster, p. 90, s'Gravenhage, 1902) is the main cause of chambering in deep-sea oysters.

The view given above on the cause of chambering in oysters could readily be put to the test of experiment, but it would be preferable to carry out experiments on a large scale, beginning with thousands of young oysters. The economic importance of oysters is sufficiently great for the matter to be taken up by such large oyster-planters as are troubled with chambering. It will readily be seen from the argument given above that chambering is a minor pathological phenomenon, and that there is nothing to prevent the growth of a good well-fished oyster in a chambered shell, and, as a fact, excellent oysters do occur in chambered shells.

The Hardness of Vitreous Silica.

THE hypothesis proposed by Sir George Beilby to account for the hardening of metals by cold-working, and accepted by most metallurgists in this country, assumes the production of a vitreous phase of the metal by the breaking down of the crystalline structure during extensive deformation. It requires that the vitreous modification of a substance should be harder than the crystalline. Direct evidence on this point has rarely been obtained. Silica, however, suggests itself as a suitable substance for such a test, both the crystalline forms and the under-cooled glass being readily obtained in a form suitable for mechanical tests. The hardness of silica was carefully studied by Auerbach, who found a surface of vitreous silica to be less hard than either of the principal faces of quartz. Most commercial silica glass is, however, so weakened by the presence of numerous gas bubbles that any grinding test is likely to give low results for the hardness.

We have recently had the opportunity of examining a specimen of silica of unusual hardness. This was obtained by throwing a quantity of pure quartz sand on to the slag in an open-hearth steel furnace when the slag surface was at an exceptionally high temperature (1800° C. by the optical pyrometer). The sand melted, and formed a lenticular mass, which only mixed with the slag at its margin. On removing the product, a colourless, translucent mass of glassy silica was obtained, passing sharply into the dark slag. Analysis of the colourless mass gave 97·7 per cent. silica, 2·0 per cent. lime, and a trace of iron. A thin section between crossed Nicols was isotropic, with only a few scattered inclusions of minute crystals and some spherical bubbles.

Tests with a sclerometer, using a diamond point under a load of 400 grams, gave a broader scratch on a prism face of quartz than on a polished surface of the vitreous silica, but on account of the splintery nature of both scratches little reliance could be placed on the actual measurements. A fractured edge of the fused product distinctly scratched the prism faces of quartz, while natural angles of the latter failed to scratch the vitreous surface. Further tests were made with the scleroscope, an instrument in which the rebound of a diamond-pointed hammer falling from a height is measured. The following figures were obtained, all the specimens being embedded in pitch in the cast-iron cup provided with the instrument:

Polished vitreous silica	94
Quartz, prism face	91
Commercial vitreous silica . . .	82

The experiments are not conclusive, and a higher accuracy will be attempted, but it would appear that silica thoroughly fused at a high temperature is distinctly harder than crystalline quartz, and to this extent the experiments support Beilby's hypothesis.

Distribution of the Organ-Pipe Diatom, *Bacillaria paradoxa*.

IN the Notes in NATURE for September 29, 1921 (vol. 108, p. 163), it is mentioned that Mr. J. W. Williams and Mr. H. Weaver have found the curious organ-pipe diatom, *Bacillaria paradoxa*, in canals and pools in Staffordshire and Worcestershire. It may be of further interest to note that while leading a party of field naturalists on a seaside expedition to Altona Bay, near Melbourne, some years ago (*Victorian Naturalist*, vol. xxxiv., June 1917, p. 16), we found this same diatom very abundantly both in the sea and up the Kororoit Creek for a good distance, where the water was only slightly brackish. On examining the finds at home I was struck with the fact that, whereas the marine form was very active in its peculiar sliding movement, the brackish form was sluggish in contrast. It would be interesting to know whether other observers have found the fresh water to act as an agent for "slowing down." Probably the saline conditions of the water assisted the osmotic pressure which may induce the movement.

Speculation concerning the Positive Electron.

SIR OLIVER LODGE'S interesting speculation, in NATURE of November 25, p. 696, as to the possible similarity of positive and negative electrons suggests an inquiry into the relative abundance of the lighter

and heavier elements to be expected on this hypothesis. Considering the simplest case, that of hydrogen, let us assume that very large equal numbers of positive and negative electrons initially combine to form $N+n$ positive, and $N-n$ negative protons, and that the negatives immediately combine with an equal number of positives to form heavier nuclei, leaving $2n$ positive protons to form hydrogen atoms. Since in the combination of protons to form heavy nuclei the loss of mass by "packing" is apparently small, the ratio $\frac{\text{mass of hydrogen}}{\text{total mass of all elements}}$ should be very nearly equal to $2n/2N$, *i.e.* n/N.

The probability that, in the fortuitous formation of $2N$ protons, $N+n$ shall be positive and $N-n$ negative is $\frac{(2N)!}{2^{2N}.(N+n)!.(N-n)!}$. This is a maximum when $n=0$. Call this probability for an exactly equal distribution P, then the probability for any other distribution is $\frac{P.(N!)^2}{(N+n)!.(N-n)!}$, which, in the limit when N is very great, reduces to $Pe^{-\frac{n^2}{N}}$. It is hence highly improbable that n^2 should be large compared with N. If we assume that $n^2=N$ we should get a result of the right order of magnitude. On this assumption the relative concentration of hydrogen would be $1/\sqrt{N}$.

Whatever may be the case in other systems, we would certainly seem to be justified in assuming that, in the solar system, all, or almost all, the atoms are of the positive nucleus type. The number of protons constituting the solar system is about $1{\cdot}2\times10^{57}$, which would give a hydrogen concentration of the order of 4×10^{-29}. As the hydrogen in the terrestrial oceans forms 8×10^{-11} of the whole mass of the solar system, there is no need to enlarge upon the magnitude of the discrepancy. A similar argument might be applied to the other light elements formed by the combination of positive and negative protons.

The above argument may be objected to on the ground that some negative protons would certainly combine with previously formed positive complexes. As, however, about half the complex nuclei first formed would be negative, so that some of the positive protons would be lost by combination with them, we would expect these effects to balance approximately, unless we assume that, when two unequal nuclei combine, the sign of the combination is determined by that of the larger constituent. On this hypothesis it is conceivable that, if the first set of nuclei formed happened to be positive, they might so direct the course of subsequent events by annexation of negative protons, and light negative nuclei, as to lead to the existing distribution of the elements.

The Hæmoglobin Distribution on Surfaces of Erythrocytes.

FROM time to time the point is brought home that factors should be discarded only when exact calculation proves them to be negligible. A case in point is the recent paper by Dr. K. Burker (Pfluger's *Archiv für die gesamte Physiologie*, vol. 195, p. 516). In this interesting paper it is shown that in mammals the weight of hæmoglobin per square micron of surface of the erythrocytes is apparently a constant equal to $31{\cdot}7\times10^{-14}$ gm. Dr. Burker has, however, assumed that the surface area of the cells is equivalent to twice the area of a circle having for its diameter the large diameter of the cell. The general opinion is that in mammals (the camel excepted) the shape of the cells is a bi-concave disc, having a circle for its horizontal projection, and a flat bi-concave ellipse for the vertical projection of which the minor axis is about one-third of the major axis (E. Ponder, Proc. Roy. Soc. 94B, p. 102). The surface area of such an erythrocyte would then be equal to that of an ellipsoid of revolution around the minor axis. It can be shown by the integral calculus that the area of such an ellipsoid (if the minor axis is equal to one-third the major) is 1·09 times as great as that of two circles with the major axis for diameter. Dr. Burker's constant is therefore equal to $31{\cdot}7/1{\cdot}09$ or 29×10^{-14} gm. hæmoglobin per square micron of surface of erythrocyte instead of $31{\cdot}7\times10^{-14}$ gm.

The Local Handbook of the British Association.

I HAVE just seen Mr. Bernard Hobson's letter in NATURE of November 4, p. 605. Mr. Hobson might have finished the quotation he gave from your review of the Hull Handbook which stated that "It approaches nearer to our ideal than that issued at any previous meeting. . . ."

Early last year Mr. Hobson wrote to me making various suggestions in connexion with the handbook, and I fancy I was able to tell him that they had all been carried out: he has now found some more. Of course no one will be able to meet the wishes of every member of the British Association in this way, but what is often forgotten is the fact that the local handbook is *presented* to the visitors *by the local committee*, and whether it is good or bad is scarcely the concern of a committee of the British Association. In our case something like 800*l.* was spent in producing a book which, we knew quite well, could not possibly be read, marked, learned, and inwardly digested during the meeting, but we felt that the book might be useful for reference after the return of the members to their respective homes.

I quite agree that an index and a geological map would have been an improvement; in fact, we went to considerable trouble in the preparation of a geological map of the Riding, but the printers' strike made its publication, indexing, etc., impossible. Only a few days before the Hull meeting none of the handbook was printed off, much was still in manuscript, and it was only by working day and night that a supply was ready for the use of the members. For the benefit of future meetings of the Association, may I suggest that the editor of the handbook should not be one of the local secretaries. Each of these tasks is quite sufficient for an ordinary human being, and for one to attempt both is almost bound to court disaster.

T. SHEPPARD.

Museum, Hull.

Occult Phenomena and After-images.

PROF. ANDRADE'S experiments recorded in NATURE of December 23, p. 843, on the apparent move ments of cardboard hands, suitably illuminated by dim light, are interesting in connexion with a phenomenon recently recounted to me by a coroner of long experience. It appears that members of the jury, when brought in to view a corpse, frequently declare that they have seen the body, sometimes of long standing, breathing. No doubt an apparent up and

down movement of the naked thorax is induced in a way similar to that recorded by Prof. Andrade. It is possible that murderers brought into the presence of the corpse of their victim exposed in a dim light must frequently have seen such movements of the hands especially as they will probably stare fixedly at the body. Any apparent movement will of course be intensified by suggestion. This may account for many old superstitions.

Finally I should like to compliment Prof. Andrade on having described certainly two of the prettiest methods of demonstrating the movements of the visual purple. I find that the phenomena described by him are readily seen by people who have not been told what they are expected to see, an essential point in such experiments.

F. W. EDRIDGE-GREEN.

London, December 26.

Experiments on Hardness and Penetration.

I AM greatly interested in the letter on "A Curious Feature in the Hardness of Metals," by Mr. Hugh O'Neill and Dr. F. C. Thompson, which appears at p. 773 of NATURE of December 9, for in my paper "Experiments with Clay in its relation to Piles," read before the Society of Engineers on March 10, 1919, will be found an account of the "pressure of fluidity" of clay. Briefly this may be described thus. When a horizontal disc resting on clay is gradually loaded it slowly sinks into the clay, each increment of load producing a corresponding increment of penetration, but when the load on the disc reaches a certain critical value the disc continues to sink at about ten times the speed *without* any further increase of the load. This load divided by the area of the disc I have called the pressure of fluidity of the clay. This quantity has been found, within a considerable range, to be independent of the area of the disc used for its determination. The only factor upon which it depends, in the case of the London clay used, is the percentage of water in the clay, and by this it is very greatly affected, as will be seen from the following equations, which fit the results closely within the ranges stated, and the table below.

From 28 per cent. to 38 per cent. of water; $p' = \frac{1073 \times 10^{10}}{w'^{5}}$, where p' is the pressure of fluidity in grams per sq. cm. and w' is the percentage of water in the clay.

The same equation may be used with small error down to $w' = 25{\cdot}7$ per cent., but with values of w' from 25·7 per cent. to 22·0 per cent. the relation is p (kilograms per sq. cm.) $= 39{\cdot}5 - 1{\cdot}48w'$.

I have experimented with spheres in place of discs and have not detected any difference in the values of the pressures of fluidity thus determined. The reason for this is probably due to what other experiments have disclosed, namely, that the descending disc carries down with it the clay which was immediately under it at the start of the experiment, this stagnant clay forming roughly a hemisphere below the disc. Whether a disc or sphere is used, a clean hole is left behind.

Expecting to find a similar phenomenon in the case of metals, a corresponding experiment was made with cast lead. The result was the same. At a certain critical load the disc continued to sink into the lead without further increment of load. The pressure of fluidity of lead was thus found to be 1233 kilos per sq. cm., as recorded at pp. 152-4 of my fourth paper on "The Physical Properties of Clay," read before the Society of Engineers on June 12, 1922. From the rate of penetration (after the pressure of fluidity had been reached) and by a modification of Stokes' Law, the viscosity of the lead at 60° F. was found to be

$$7{\cdot}37 \times 10^{10} \text{ dyne-seconds per sq. cm.}$$

Taking the Brinell formula given by Messrs. O'Neill and Thompson, when the ball is below the surface of the material $d = D$, and the Brinell formula they give becomes

$$H = \frac{2L}{\pi D^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

And when $d = D$ the Meyer formula becomes

$$L = aD^n \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Substituting (2) in (1) we have

$$H = \frac{2aD^n}{\pi D^2} = \frac{2a}{\pi} D^{n-2} \quad . \quad . \quad . \quad . \quad (3)$$

The Brinell hardness number is the stress in kilograms per sq. mm. on the curved surface of the indentation.

The pressure of fluidity, p, is the critical load L divided by the area of the disc (or great circle of the ball). Thus:

$$p = \frac{L}{A} = \frac{L}{\frac{\pi}{4}D^2} = \frac{aD^n}{\frac{\pi}{4}D^2} = \frac{4a}{\pi} D^{n-2} \quad . \quad . \quad . \quad (4)$$

Hence p is seen to be equal to 2H, where $H = \frac{2L}{\pi D^2}$ and L is the critical load.

This result also immediately follows from the fact that in the case of the Brinell No. the load is divided by the area of the *curved* surface of the indentation, whereas in the case of the pressure of fluidity the load is divided by the projected area of the sphere, and the ratio of the area of the curved surface of a hemisphere to its flat surface is 2.

$$\text{As } A = \frac{\pi}{4}D^2, \quad \therefore D = 1{\cdot}13\sqrt{A},$$

Therefore Meyer's formula

$$L = aD^n \text{ becomes } L = a(1{\cdot}13\sqrt{A})^n$$

$$= a(1{\cdot}13)^n A^{\frac{n}{2}}.$$

But in the case of clay, $L \propto A$, this being one of the most definite and carefully determined results. Consequently, if Meyer's formula is also true for clay, n must be $= 2{\cdot}0$, in which case $L = a(1{\cdot}13)^2 A = 1{\cdot}275aA$, and $L/A = p = 1{\cdot}275a$ or $a = p/1{\cdot}275$.

Using this relation the following values of a are obtained for London clay:—

Per cent. of Water.	Pressure of Fluidity. Kilos per sq. cm.	a.
37·8	0·107	0·083
37·0	0·128	0·100
31·0	0·320	0·251
30·0	0·527	0·414
29·0	0·600	0·471
28·0	0·846	0·663
25·4	1·938	1·521
23·6	4·700	3·69
22·0	7·200	5·65

A. S. E. ACKERMANN.

December 11.

The Borderland of Astronomy and Geology.[1]

By Prof. A. S. EDDINGTON, F.R.S.

THE region in which geology and astronomy most conspicuously overlap is in the theories of the origin of our planet. We have, in fact, two main theories—one due originally to an astronomer, Laplace, and the other to a geologist, Chamberlin.

In the last century the evolution of a star seems often to have been regarded as something quite detached from the evolution of the stellar universe. Just as the birth and death of a man is an incident which can occur at any time in the rise and decline of the human race, so it was thought that the birth and extinction of a particular star formed merely a detached incident in the course of progress of the stellar universe—if, indeed, the universe was progressing in any particular direction. Thus it was a natural belief that the stars died out and were re-formed by collisions of extinct stars; and that the matter which now forms the sun had undergone many alternations of incandescence and extinction since things first began. But this view is quite at variance with the general tendency of sidereal astronomy in the present century. We have come to recognise that the stellar system is one great organisation, and that the stars which are shining now are more or less coeval with one another. Everyone would admit that Mars and Jupiter were formed as parts of one process of evolution—not necessarily at the same moment, but each formed as the process reached the appropriate stage; and similarly we now believe that it was one process of evolution sweeping across the primordial matter which caused it to form itself into stars; and these original stars are the actual stars which we see shining now. No doubt the evolution did not develop at the same rate in all parts of the universe, and there are probably places where stars are still being formed; but you will see that this view is entirely different from the other view that stars were being formed individually by haphazard collisions of dark stars, so that each was an independent formation, having no time-connexion with other stars.

This view has been forced on us partly by direct evidence of organisation among the stars, pointing to a common origin for large groups of stars. We notice scattered groups such as the Hyades, which have almost exactly equal and parallel motions. Clearly it would be impossible to form such a group if each star were the product of an accidental collision. The only way in which a common motion like this can arise is by associated development from some nebula or other diffuse distribution of matter. The connexion is clearly a connexion of common origin. Again, practically all the bright stars of Orion form a similar group, having common motion; and, moreover, they have all reached a similar stage of evolution. They are connected with the great Orion nebula, the faint extensions of which fill up nearly the whole constellation. It is obvious that here we have to deal with a single evolutionary development. But another point which militates against a collision theory is the extreme rarity of collisions and close approaches. The distances separating the stars are enormous compared with their own dimensions. Sir Frank Dyson once used the illustration of twenty tennis-balls, distributed at random throughout the whole interior of the earth, to give a model of the density of distribution of the stars. It has sometimes been objected that we do not know how many extinct stars may be wandering about and colliding. Dyson's twenty tennis-balls represent only the *luminous* stars; there may, for all we know, be millions of *dark* bodies ready to be fired into incandescence by collision. I think, however, that there is now good evidence, based on the dynamics of stellar motions, that the dark stars cannot greatly outnumber the luminous stars—probably not ten times and certainly not a hundred times. (If they were more numerous than that, the average velocities of stars would, owing to the gravitational attraction, be much higher than is observed.) That argument, then, is no longer valid. Taking a very liberal view of the kind of approach that can be held to constitute a collision, it is estimated that a star would only suffer collision once in 10^{14} years.

Thus the astronomer is not predisposed to look favourably on a hypothesis of the origin of the solar system which postulates anything of the nature of a collision. He has the conception of an orderly development of the stars crystallising out of the primordial material, and, unless perhaps in exceptional cases, following an undisturbed course of development. We hope for a theory that will show us the star after its first isolation from surrounding material spontaneously developing the system of planets.

It now appears almost certain that, whether the original matter was gaseous or whether it was composed of meteors, it must at an early stage in the star's history have been completely volatilised into gas. This was while the star was extremely diffuse, and, for example, before the planets separated from it. This means that the material now forming a planet has at one time passed through the furnace, and has cooled down from a gaseous stage. How far that has a direct bearing on geology I cannot say, since I have nothing to guide me as to the course of its subsequent chequered history. I do not say that the earth was a gaseous body when it first became recognisable as an independent planet, but I am convinced that its material was at one time merged in a completely gaseous sun.

It may be of interest to indicate why it seems so probable that a star in its early diffuse state is gaseous and not meteoric. The stars are known to be of closely similar mass. There are occasional exceptions, but probably 90 per cent. of them are between one-half and five times the sun's mass. We have no explanation of this uniformity if they are initially merely aggregations of solid meteors; but we have a very exact explanation if they are gaseous. In fact this critical mass round which the actual masses of the stars cluster so closely is predicted by the theory of equilibrium of spheres of gas, using only well-known physical constants determined in the laboratory. The crucial factor is radiation-pressure, which is inappreciable in smaller masses, and almost suddenly takes control between one-half and five times the sun's mass.

[1] A lecture delivered before the Geological Society of London on November 21.

There can be little doubt that large radiation-pressure, tending to overcome gravity, conduces to instability, so that larger masses have small chance of survival. Somewhere about one-half the sun's mass the radiation-pressure no longer counts seriously, so that there is no tendency for the primitive material to break into smaller units.

The existence of radioactive minerals on the earth seems to supply another reason for believing that its material was originally subjected to high temperature or to physical conditions of a different order from those now prevailing. In radioactivity we see a mechanism running down which must at some time have been wound up. Without entering into any details, it would seem clear that the winding-up process must have occurred under physical conditions vastly different from those in which we now observe only a running-down. The only possible guess seems to be that the winding-up is part of the general brewing of material which occurs under the intense heat in the interior of the stars.

The trend of this argument has been against the Chamberlin-Moulton hypothesis and in favour of some form of nebular origin of the solar system. It is, of course, accepted that the details of the original nebular hypothesis of Laplace require modification. Also the word nebula is meant to signify diffuse gaseous material in general, and has no immediate connexion with those objects which we see in the sky, and call nebulæ more particularly. There is still controversy as to what process of evolution is represented by the spiral nebulæ which are seen in such numbers—what they will ultimately turn into; but the controversy is whether the spiral nebula will give rise to a cluster of a few hundred stars, or whether it will turn into a stellar universe on the same scale as the great system of some thousands of millions of stars which forms our galactic system. There is now no suggestion that it has anything to do with the formation of so insignificant a system as the solar system. But in preferring the nebular hypothesis to that of Chamberlin and Moulton, it is necessary to make a certain reservation. We have hitherto taken it for granted that the formation of a system of planets is a normal feature of the evolution of a star. Most of my arguments have referred to the development of stars in general, and would become irrelevant if it could be admitted that the solar system were an exceptional formation violating ordinary expectation.

We know that at least a third of the stars are double stars, and I do not think there is any reason to think that planetary systems would be formed when the evolution takes that course; but until recently it was taken for granted that the remaining single stars would generally (or at least frequently) be the rulers of systems of planets. Jeans has recently pitched a bombshell into the camp, suggesting that the solar system is a freak system—the result of a rare accident, which could only happen to one star out of a very large number. He found no way of accounting for it as a normal process. I have not the specialist knowledge necessary to criticise the details of the working of the nebular or of the planetismal theory of development, but before regarding Jeans's argument as conclusive (he himself makes reservations) I should be more satisfied if the effect of radiation-pressure had been taken into account. It is fairly clear that radiation-pressure plays a great part in the separation of nebulous matter into stars, and although I have no definite reason to think that it can account for the separation of planets from the sun, I do not feel satisfied that we have got at the whole truth until that point has been duly examined.

Supposing, however, that we are forced to accept Jeans's suggestion that the solar system is a freak system, some of my objections to the Chamberlin-Moulton hypothesis are removed. I cannot admit that the conditions of collision which that hypothesis requires are normal features in the formation of stars; but they might have happened occasionally in the history of the universe, and produced the solar system, the sun being thus as an exceptional star born out of due time. But if my arguments against Chamberlin's hypothesis fall to the ground, there are probably other astronomers prepared to attack it in other directions.

The new views as to the age of the earth are now pretty well known to geologists. I may sum them up briefly in the statement that Lord Kelvin's estimate of the extent of geological time need not now be taken any more seriously than Archbishop Ussher's, and that the geologist may claim anything up to 10,000 million years without provoking a murmur from astronomers. Although there may still be some difficulties about the exact source from which the vast heat-energy the stars pour out into space is derived, it is now clear that the Helmholtz contraction-theory is inadequate to give the necessary supply. The astronomer has no such precise means of measuring geological time as the physicist has now discovered by the analysis of radioactive minerals; but he can add his contributory evidence that the sun, and presumably therefore the earth, is much older than Lord Kelvin allowed. In the Cepheid variable stars it seems possible to measure the actual rate at which evolution is proceeding—the rate at which the star is condensing from a diffused state to a denser state. The star is believed to be pulsating, and as it expands and contracts the light varies in quantity and character. In a pulsating gravitating mass the period is proportional to the inverse square root of the density, so that by observing the rate at which the period is changing we can deduce the rate at which the density is changing. I may add that the law that the period depends on the inverse square root of the density is very closely confirmed by comparing the values for the various Cepheids. In this way we find that for the best observed of these stars, δ Cephei, the density is changing 500 times slower than the contraction hypothesis assumes. It would, of course, be risky to assume that the same proportion holds at all stages of the evolution of a star; but it suggests that Lord Kelvin's estimate of 20 million years for the age of the sun might well be multiplied by 500 to give 10,000 million years. At any rate, the Cepheid observations show that the stars must have some other source of energy besides contraction.

I suppose it must be a matter of interest to geologists whether the intensity of the sun's heat has been constant or whether it was at one time hotter than

now. I think we can say fairly definitely that the sun was formerly much hotter. There must have been a time when the sun's heat was from 20 to 50 times more intense than it is now. That would no doubt have made a great difference to many geological processes. Unfortunately, I cannot say whether it occurred in known geological epochs. It must have occurred after the earth had begun to exist as a separate planet; but whether it was before or after the sequence of geological strata began to be laid down I have no idea. It would not be unreasonable, however, to expect that in the early geological times the sun was several times hotter than it is at present.

After the evolution of the solar system, we naturally turn to consider the evolution of the earth-moon system. My impression is that nothing in recent progress suggests any doubt that the beautiful theory of Sir George Darwin is substantially correct. The main features are that the moon at one time formed part of the earth, and broke away. At that time the rotation period of the earth was between 3 and 4 hours, and the cause of the fracture was that the solar tidal force synchronised with a free period of natural vibration of the earth; owing to resonance the tidal deformation of the earth continually increased until rupture occurred. The earth's period of rotation has since lengthened to 24 hours, owing to frictional dissipation of energy by lunar and solar tides; and the back-reaction of the lunar tides on the moon has caused the moon to recede to its present considerable distance. All this has well stood the test of searching criticism, and must be considered as extremely probable. Modern research has added two contributions; it enables us to calculate the magnitude of this tidal friction at the present time, and it enables us to locate more exactly the region where the frictional dissipation is occurring.

I believe it was Darwin's view that the tides most potent in wasting energy were not water-tides but tides in the solid earth; that is to say, we have to do with deformations of the whole earth under the tide-raising force of the moon's attraction. Undoubtedly these deformations of the earth occur, but everything turns on whether the process of deformation is attended with serious friction. H. Jeffreys has pointed out that the phenomenon of latitude variation is accompanied by similar deformations of the earth; and in this case it is clear that the friction is inconsiderable, for otherwise the deviations of the pole from the symmetrical position would be damped out almost at once. It seems, therefore, very unlikely that the solid tides can have had much effect in the process of tidal evolution of the earth-moon system. Ocean tides are likewise of small effect as Darwin himself had seen. The modern conclusion is a very curious one; it is in the land-locked shallow seas that nearly all the mischief occurs. This was discovered by G. I. Taylor, who found that the Irish Sea alone is responsible for $\frac{1}{50}$ of the whole amount required by observation. The remaining land-locked basins on the earth are probably capable of making up the necessary total.

The actual rate at which the earth's rotation is being slowed down at the present era can probably be deduced with fair accuracy from the records of ancient eclipses. The day is lengthening about one-thousandth of a second per century or 1 minute in 6,000,000 years. At this rate we should have to go back more than 10,000 million years to the time when the day was between 3 and 4 hours and the moon was born. Since the rate depends on the accidental circumstance of occurrence of shallow seas no definite prediction can be made; but allowing for the much greater effect of the tides when the moon was nearer to us, it is difficult to date the birth later than 1000 million years ago.

Had the earth a solid crust at the time the cataclysm happened? I cannot tell at all. But if it suits geological theories I can see no objection whatever to the hypothesis that the earth had a solid crust at the time. No cohesion of the crust would seriously resist the enormous forces involved when the resonant vibration got started. It would not be appreciably more difficult than the disruption of a molten earth. The view that the Pacific Ocean is the hollow left at the place where the moon broke off seems tenable unless geologists find objection to it; and in that case we may suppose that the water now collected in the hollow formerly covered the earth—or most of it. This change of condition of the earth may (or may not) have happened within geological times. When the earth was covered with water there would be no land-locked seas and no appreciable tidal friction from the sun (the moon being not yet born), so that we can allow a long previous history during which the length of day was nearly constant at 3 or 4 hours. That rather helps to make the whole theory self-consistent.

These speculations stand very much as they did when Darwin put forward his theory. But I am tempted to add further speculations arising out of the location of the frictional dissipation. (I am taking advantage of the great opportunity for speculation which this address affords. Ordinarily I am restrained, because people would ask, What facts can you produce in support of your speculations? But here I am asking the question, Have you any facts which seem to support them? If not, by all means let them drop.) The frictional dissipation acts as a brake on the earth's rotation, and we now feel confident that the brake is a surface-brake applied at certain points on the earth's surface where the favourable conditions exist. The retarding force is transmitted to the earth's interior, and so delays the rotation as a whole; but unless the material is entirely non-plastic there will be a tendency for the outer layers to slip on the inner layers. I do not know how much the material a few hundred miles below the surface would be expected to give under the strain; it may be inappreciable, but I will assume that though small it has some effect.

We have then the whole crust slipping from east to west over the main part of the interior. Probably it would go very stickily, sometimes arrested by a jamming which would hinder it for a time and then going on more easily. That is helpful in explaining certain astronomical observations. There are irregularities in the motions of heavenly bodies, noticed particularly in the swift-moving moon but shown also on a smaller scale in the sun and planets, which appear to indicate that our standard timekeeper, the earth, is a little irregular. Now, of course, it is the rotation

of the *surface* of the earth which determines our standard time. I find it difficult to believe that there can be irregular variations in the angular velocity of the earth as a whole; but it seems less difficult if the variations are merely superficial, due to the crust sliding non-uniformly on the interior. I have even entertained the wild idea that the motion of the magnetic poles might be due to this cause; the magnetism being constant in the interior but with the axis emerging at changing points of the crust as the crust slips over the inner magnet. Unfortunately, so little seems to be known about the motion of the magnetic poles that I have not even been able to make out whether the motion is from west to east as this theory definitely requires.

What interests the geologist more nearly is that the brake is applied only at certain areas on the surface, so that there would be a tendency to crumple the crust more particularly to the west of these areas. It is unfortunate that shallow seas are necessarily the least permanent features of the earth; otherwise I would have asked whether the geologists had evidence of special crumpling in such areas.

I have regarded the crust as fairly mobile from east to west. I suppose the geologists would also like it mobile from north to south in order to have glacial periods in those portions which are now near the equator. It is not possible to hold out much encouragement for such an idea, because we cannot imagine any force acting from north to south. Still if the crust, which is being urged by the east-west force of tidal friction, is resisted by obstacles it may be deflected, finding that say a south-west track offers less resistance. In a long enough time almost any displacement may have happened, granting my hypothesis that the connexion of the crust to the interior is reasonably plastic. So I cannot forbid this possible interpretation of glacial periods in the earlier geological times.

I am sure that it will not be supposed that, in presenting the astronomical side of these questions which belong both to geology and astronomy, I have any intention of laying down the law. The time has gone by when the physicist prescribed dictatorially what theories the geologist might be permitted to consider. You have your own clues to follow out to elucidate these problems, and your clues may be better than ours for leading towards the truth. We both recognise that we are adventuring in regions of extreme uncertainty where future discoveries will probably lead to various modifications of ideas. Where, as in the new views of the age of the earth, physics, biology, geology, astronomy, all seem to be leading in the same direction, and producing evidence for a greatly extended time-scale, we may feel more confidence that a permanent advance is being made. Where our clues seem to be opposed, it is not for one of us to dictate to the other, but to accept with thankfulness the warning from a neighbouring science that all may not be so certain and straightforward as our own one-sided view seemed to indicate.

Nature and Reproduction of Speech Sounds.[1]

By Sir RICHARD PAGET, Bart.

ALL the characteristics of English speech—the vowels and diphthongs and consonant sounds—can be produced—as breathed or whispered speech—without using the larynx at all; so that in the use of the English language (at least) it may be said that the larynx is not an essential organ of speech. The function of the larynx is to give carrying power and inflexion to speech, and melody to song—it has nothing to do with the essential characteristics of speech.

If any one with a normal "ear for music" will whisper the words "Noah's rather at sea"—thinking of the sounds rather than of the sense—they will hear

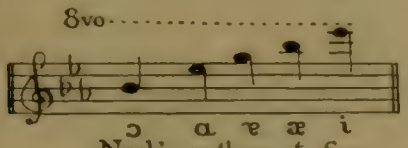

FIG. 1.

an ascending arpeggio something like the phrase shown in Fig. 1. The exact notes heard in each case will depend on *how* the individual person pronounces the vowel sounds in question.

These whispered or breathed notes are formed, as is well known, by the resonance of the cavity of the mouth, and they are varied for each different vowel sound by altering the size of the cavity and the opening of the mouth, mainly through the operation of the tongue and lips. With many of the vowel sounds, namely, **i** (eat), **ei** (hay), **e** (men), **æ** (hat), **o** (not), and in some types of **ɑ** (calm), two simultaneous resonant notes have been heard by many investigators, but the remaining principal vowel sounds, **ɔ** (all), **ou** (no), and **u** (who), have been generally supposed to be characterised by a single resonance.

Some observations made by me at the beginning of this year, using my own breathed vowel sounds, indicated that in *every* case the mouth—or rather the oral cavity as a whole, from the larynx to the lips—actually gives *two* simultaneous resonances for *each* vowel sound. It appeared that these pairs of resonant notes are not fixed in pitch for any one vowel sound, but might vary over three or four semitones—and sometimes even more—without a very appreciable change in the character of the vowel.

The resonances heard in the use of my own voice are set out in the accompanying chart, in which the vertical scale represents semitones of the equal temperament scale, and the vowel sounds are represented in the notation of the International Phonetic Association (Fig. 2).

It will be seen that **i** (eat), **I** (it), **ei** (hay), **e** (men), **æ** (hat), **ɐ** (earth), **ə** (sofa), **ʌ** (up), and **ɑ** (calm) form very nearly a converging series—the upper resonances falling by steps of 1 to 3 semitones, while the lower resonances are more active and take larger jumps—

[1] Substance of a lecture delivered at University College, University of London, on October 18.

not all in the same direction. From ɑ (calm) onward the resonances go down, as it were, hand-in-hand, keeping an equal distance of about 8 semitones apart; and it is possible, owing to this fact, that they have not been generally recognised as separate resonances.

The double resonance of the oral cavity when forming the vowel sound u (who) may be demonstrated by the clapping method (see NATURE, March 16, vol. 109, p. 341); also the possibility of varying both resonances independently at the same time. Similarly, the independence of the larynx note and the front resonance may be illustrated by simultaneously humming and whistling a convergent scale.

Having identified the various resonances on which

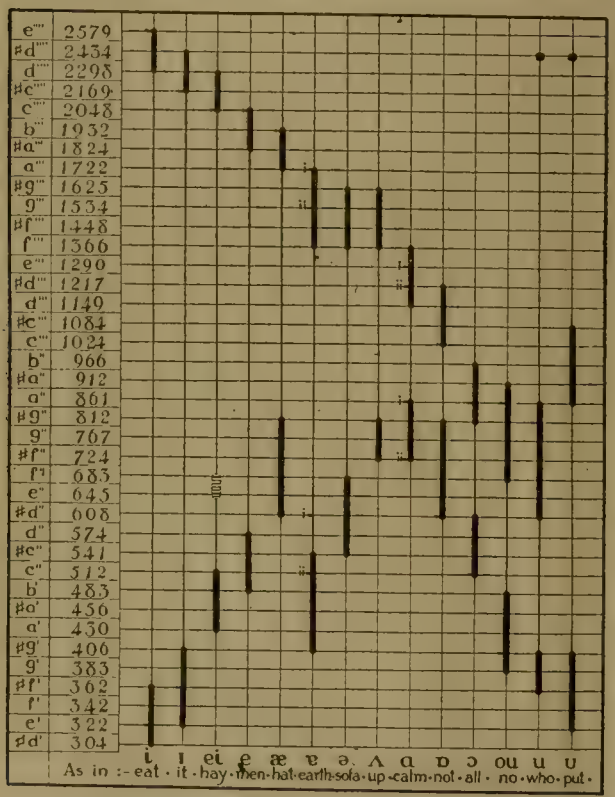

FIG. 2.—Vowel resonance chart. The horizontal dashes on the thick vertical lines denote the actual resonances of the models; the numerals i, ii denote successive models of the same vowel.

the production of the breathed vowels appeared to depend, the attempt was made to reproduce these vowel sounds by constructing some form of resonator which had resonances identical with those of the human mouth when a stream of air was blown through it. It seemed reasonable to expect that, if this could be done, the breathed vowel sounds would be reproduced. Models in plasticine were therefore made, the internal form of which very roughly imitated that of the human mouth and throat, except that the back portion corresponding to the pharynx was, for convenience, shortened and made more bulbous.

With this and similar models a number of experiments were made to test the effects of various alterations of the internal form—such as are actually made in the human mouth by the movement of the tongue, lips, etc.—and to discover the rules for tuning the instrument. An artificial larynx was made of a rubber strip lying across a flattened air passage—on the principle of the reed instrument which boys make with a blade of grass held between their two thumbs. When this reed or larynx was fitted to the back orifice of the model and blown, the model gave a voiced vowel.

The rules for tuning these models may be shortly summarised as follows: Enlarging the mouth generally raises both resonances. Increasing the projection of the lips or reducing the size of the mouth lowers both resonances. Raising the front of the tongue upwards or forwards raises the upper resonance but lowers the lower resonance. Pressing the back portion of the tongue backwards—so as to reduce the capacity of the back cavity corresponding to the human pharynx and to prolong the passage between the front and back cavities of the mouth—raises the lower resonance but lowers the upper resonance.

The experiments in tuning the plasticine cavities eventually made it clear that the human mouth, when making vowel sounds, always acts as *two separate "Helmholtz" resonators connected in series*—one behind the other—the back resonator being formed by the pharynx, the back of the tongue, and soft palate; the front resonator being formed by the front of the tongue, the hard palate, and lips; and the passage between the two resonators being formed by a hump in the middle of the tongue which approaches the roof of the mouth. By humping the tongue in different positions—forward or backward—the relative sizes of the front and back resonators can be altered at will, while the tuning can further be modified over a wide range by varying the opening of the mouth.

The resonant note of a cavity with an orifice to the open air depends, as is well known, on the relation between the volume of the cavity and the size of its orifices. The larger the cavity the lower the note; the larger the orifice the higher the note. With a resonant cavity having a neck—such as the neck of a bottle—the resonant pitch also depends on the length of the neck, being lower as the neck is made longer, and higher as the neck is shortened.

It follows from this that when two such resonant cavities are joined together, each one becomes, as it were, a neck to the other, and therefore influences its pitch. The effect is always to lower more or less the resonance of the neighbouring resonator according to the relation of the relative sizes of the two, and of the relative sizes of the connecting opening between the resonators and the opening to the air of the front resonator. The pitch of the resonators was ascertained by tapping them and listening to the resonant notes, or by blowing across the open mouth.

Each of the plasticine models (Fig. 3) made on this principle gives two resonances corresponding to a separate vowel sound. When the various models are blown in succession, first by mouth and afterwards for ɐ (earth) and ɔ (all) by bellows, the vowel characters are made more recognisable by covering and uncovering the mouth of the model by hand during blowing, so as to give an associated consonant (m or w). It was thus demonstrated that the vowel sound remains appreciably constant however much the pitch of the larynx note is altered by varying the air pressure.

Instead of putting the two resonators in series, as

already described, they may be placed in parallel—side by side—with a single larynx having a forked or bifurcated passage to communicate with each of them. Two models made on this principle—one tuned to give i (eat) ♯d‴′2434 and f′342 and the other to give ʌ (up) g‴1534 and ♯g″812—when blown emit vowel sounds practically the same as those given by the corresponding resonators in series with a single mouth.

Certain vowel sounds can be produced by a single cylindrical or ovoid resonator. An egg-shaped plasticine resonator, when blown *through* by means of a small hole at the back, gave three resonances—c″512, g‴1534, and c⁗2048, and a vowel sound intermediate between e (men) and ɐ (earth).

Double resonances may also be obtained from a cylindrical resonator closed at one end and blown through a small orifice in the closed end. A reed-actuated cylindrical resonator of variable length (lent by Prof. D. Jones) gave a series of vowel-like sounds, and a plasticine cylindrical resonator gave ʌ (up) with resonances ♯g‴1625 and ♯g″812.

These cases of double resonances produced by a single resonator are interesting as affording a possible explanation of Helmholtz's statement, that he had obtained certain vowel sounds by the use of a single resonator.

The reproduction of the various consonants appears to depend on exactly the same principles, namely, the combination of separate resonators (sometimes more than two), and it has been found possible to reproduce all the English consonant sounds also in this way. The principal difference is that, whereas with the vowels (other than the diphthongs) the resonances are more or less fixed during the voicing of each vowel, with most of the consonants the resonances are rapidly changing, and the consonant sound depends to a large extent on the rate of change.

To summarise these experiments and conclusions: We have seen that each of the English vowel sounds, when whispered or breathed, appears to consist of two musical notes due to the air current from the lungs blowing through the cavity of the mouth and throat. The cavity as a whole is divided up by the tongue into two resonating cavities—one behind the other—each of which produces its characteristic note.

When, instead of passing a steady current of breath through these resonators, we pass a current of air which has previously been set in vibration by the action of the larynx, the sound of the larynx note is coloured by the two resonators respectively and acquires the character which we recognise as voiced vowel sound.

The two resonances which characterise each of the different vowel sounds are not absolutely fixed in pitch for each vowel sound but may vary over several semitones; the tuning of the resonances is performed, in the mouth, mainly by the action of the tongue and lips, and is quite independent of the vibrations of the larynx.

In models, the double resonance of the human mouth can be reproduced by pairs of Helmholtz resonators joined together in series (making proper allowance for the reaction of each resonator on the resonating pitch one of the other) or by placing the resonators in parallel, side by side, so as to produce a double-mouthed model. When the resonators are driven tandem, the leader and wheeler may be counterchanged—so that, for example, the lower resonance is given by the front resonator instead of by the back, and *vice versa*.

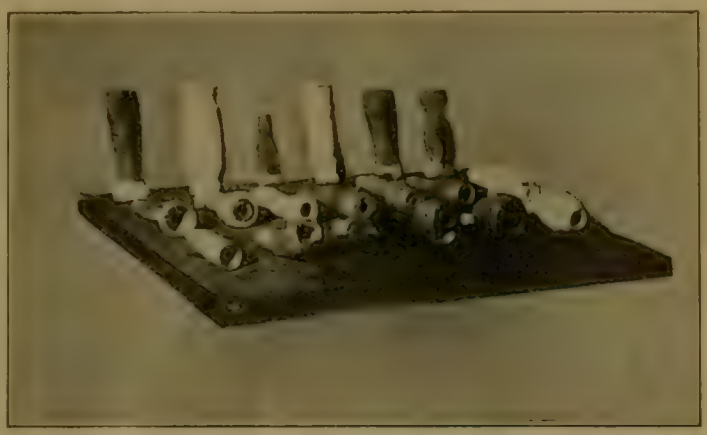

FIG. 3.—Plasticine resonators.

It follows that it should be possible to write down any vowel sound in musical notation, and to reproduce it by means of a suitable instrument designed to give any required pair of resonances, either in series or in parallel. It also follows that every one who can recognise vowel sounds must have a perfect ear for music, and an almost absolute sense of musical pitch.

Obituary.

C. L. WRAGGE.

BY the recent death of Mr. Clement L. Wragge, formerly head of the Weather Bureau at Brisbane, at Auckland, New Zealand, meteorology has lost an enthusiastic worker. Mr. Wragge was born at Stourbridge on September 18, 1852, and was educated at Uttoxeter Grammar School. After a short period of service in the Surveyor-General's department at Adelaide, he returned to England, where he founded several meteorological stations in North Staffordshire.

When the Scottish Meteorological Society wished to establish a meteorological observatory on Ben Nevis at 4400 feet above sea level, they were fortunate in securing the services of Mr. Wragge, who during the summers of 1881 and 1882 daily ascended the mountain and took regular observations. The Scottish Meteorological Society, in an appeal for public funds to found a permanent observatory on Ben Nevis, referred to "the observations made by Mr. Wragge with such skill, endurance, and enthusiasm during the last two summers on Ben Nevis." That very considerable endurance was

required for the work was graphically shown in an article in the *Times* for September 1, 1881.

Returning to Australia, Mr. Wragge served as Government Meteorologist for Queensland from 1887 to 1902, and he established the Weather Bureau at Brisbane, as well as high-level meteorological stations on Mount Wellington and Mount Kosciusko (7336 feet).

Mr. Wragge was an enthusiastic devotee of map meteorology, and in tracing the movements of cyclones and anticyclones he was accustomed to give these systems Christian names in his official reports. His views and methods, especially in later years, were frequently unorthodox.

David Lindsay.

One of the pioneer explorers of Australia has passed away recently at Port Darwin in the person of Mr. David Lindsay. Born in June 1856 at Goolwa, South Australia, of Scottish parents, Mr. Lindsay entered the State Survey Department as a youth, and in 1883 was selected to lead an expedition to Arnhem Land.

In 1888 Lindsay rode across the little known interior of the continent taking only a native boy as companion. His route took him to the Macdonnell Ranges, to which he returned shortly afterwards for more detailed examination. Mr. Lindsay's most fruitful expedition was in 1891, when he was chosen to lead the expedition equipped by Sir T. Elder for the exploration of the great Victoria desert of Western Australia. Using camels for transport, he crossed 550 miles of desert in 35 days and was able to amplify the work of E. Giles, who had crossed that district fifteen years previously. On his return Mr. Lindsay directed attention to the existence of large auriferous areas in the interior. The outcome of his report was the development of the West Australian goldfield, which he continued to explore for some years.

At a later date Mr. Lindsay returned to the examination of the Northern Territory and in 1913 was nominated to a Commonwealth Commission charged with considering the economic development of the north. In 1920 he reported the discovery of large tracts of well-watered land which had previously been regarded as desert, and he directed attention to the possibilities of cotton growing in the Northern Territory.

Current Topics and Events.

The list of New Year honours includes the names of the following men distinguished by their scientific work or associations :—*Knights* : Prof. D. Drummond, Vice-Chancellor of the University of Durham ; Dr. W. H. Hamer, Medical Officer of Health for London ; and Dr. B. H. Spilsbury, hon. pathologist to the Home Office. *C.B.* : Dr. F. J. H. Coutts, Senior Medical Officer, Ministry of Health. *C.I.E.* : Dr. N. Annandale, director of the Zoological Survey of India ; Lieut.-Col. A. T. Gage, Indian Medical Service, superintendent of the Royal Botanic Garden, Calcutta, and director of the Botanical Survey of India, Bengal ; and Mr. F. A. Leete, Chief Conservator of Forests, Burma. *K.B.E.* : Prof. D. Orme Masson, F.R.S., professor of chemistry in the University of Melbourne. *C.B.E.* : Dr. J. W. Evans, F.R.S., a member of the governing body of the Imperial Mineral Resources Bureau ; and Mr. F. E. Smith, F.R.S., director of Scientific Research, Admiralty.

It is gratifying to learn that Pasteur's centenary was celebrated at Lahore (India) on November 22 last, under the auspices of the Society for Promoting Scientific Knowledge. A conversazione was held at the rooms of the society and demonstrations given relating to Pasteur's researches. Great interest was taken by the public in the exhibits relating to crystals, silk-worms and their diseases, and microbes of various kinds shown under the microscopes. This was followed by a public meeting, at which Prof. B. L. Bhatia, president of the society, spoke on Pasteur's work in the biological field. Principal A. S. Hemmy, of the Government College, and Lieut.-Colonel C. A. Gill, of the K.E. Medical College, delivered speeches relating to Pasteur's work in the domains of chemistry and bacteriology respectively.

The latest accounts of the Chilian earthquake of November 11 are mainly concerned with the destructiveness of the shock and accompanying sea-wave. The *Times* for December 28 contains the report of a correspondent who visited Copiapo and Vallenar five days after the earthquake. The meizoseismal area is sparsely populated, the towns within it containing only a few thousand inhabitants, most of whom dwelt in low adobe or wooden houses, and this no doubt accounts for the comparatively small loss of life. At Vallenar, which suffered most, there is not a house left standing that is fit to live in, yet, out of a population of 5500, not more than 600 persons were killed and a thousand injured. Interesting photographs, showing the completeness of the destruction by the sea-waves at Coquimbo and Chañaral, are reproduced in the *Times* for December 19 and 28.

At the meeting of the London Mathematical Society on January 18 at 5 o'clock, in the rooms of the Royal Astronomical Society, Burlington House, Mr. L. J. Mordell, reader in pure mathematics in the University of Manchester, will lecture on "An Introductory Account of the Arithmetical Theory of Algebraic Numbers, and its Recent Developments." Members of other societies, or any one who wishes to learn something concerning the theory of ideal numbers, will be welcomed.

A tribunal of investigation into the agricultural problem has been appointed as follows : Sir William Ashley, professor of commerce and vice-principal of the University of Birmingham ; Prof. W. G. S. Adams, Gladstone professor of political theory and institutions, Oxford ; and Prof. D. H. MacGregor, Drummond professor of political economy, Oxford.

Mr. C. S. Orwin, director of the Institute for Research in Agricultural Economics at Oxford, has been appointed agricultural assessor to the tribunal, and Mr. D. B. Toye, of the Ministry of Agriculture and Fisheries, will act as secretary.

IT is announced that Messrs. Ashton and Parsons, Limited, have made to Guy's Hospital the generous gift of 2600*l.*, to be paid in six and a half yearly instalments of 400*l.* each. This money is to be spent in research on diabetes and related metabolic disorders, and to be called a Parsons fellowship. At the present time, much work is required in investigating the properties and methods of preparation of extracts of the pancreas, one of which is known as "insulin." This endowment will assist to a notable degree the work already for some time in progress at Guy's Hospital in connexion with the pathology of diabetes.

PROF. W. M. FLINDERS PETRIE has consented to give a lecture on "Royal Burials in Egypt," with special reference to recent excavations in Egypt, on Tuesday, January 23, at 5.30, in University College, London. The lecture will be illustrated by lantern slides, and the proceeds will be given to the St. Christopher's Working Boys' Club, which is connected with the Union Society and Women's Union Society of the College. A leaflet containing full particulars as to the prices of the tickets can be obtained by sending a stamped addressed envelope to Dr. Walter Seton, University College, Gower Street, W.C.1.

THE Council of the Royal Statistical Society will, in November next, award the Frances Wood Memorial Prize, value 30*l.*, for the best investigation of any problem dealing with the economic or social conditions of the wage-earning classes, the subject to be chosen by the competitor and treated on statistical lines. Competing essays (which must be either printed or typed, and accompanied by copies of all statistical tabulations), must be sent to the Honorary Secretaries of the Royal Statistical Society, 9 Adelphi Terrace, W.C.2, not later than July 1, 1923.

THE *Times* reports that a wireless message has been received *via* the radio station at Spitsbergen from Capt. Wisting, of Amundsen's Norwegian North Polar expedition. The *Maud*, which left Cape Hope, Alaska, on July 26 for her drift across the polar basin, met pack ice in about lat. 70° N. Pushing through the ice the ship was near Herald Island on August 7, and on August 22 was frozen into the pack in lat. 70° 20′ (? 72° 20′) N., long. 175° 25′ W. The drift first carried the vessel back to lat. 72° N. and then to lat. 73° N., and finally due west. On December 15, when the message was despatched, the *Maud* was in lat. 73° 20′ N., long. 173° W. (? E.). On September 26 the *Maud* was exposed to heavy pressure but rose uninjured, the ice meeting below her. The message reports that fine weather has been experienced and that scientific work is proceeding satisfactorily. Contrary to expectation, animal life is scanty, but a few seals and two bears have been secured. This is the first message beyond two brief weather reports that has been received since the *Maud* left Alaska. Capt. Amundsen is wintering in Alaska ready to attempt his flight to Spitsbergen next summer.

THE Research Medal of the Worshipful Company of Dyers has recently been awarded to Prof. G. T. Morgan for a dissertation on the co-ordination theory of valency in relation to adjective dyeing. This comprehensive theory of chemical affinity, propounded originally by A. Werner of Zürich, offers a means of correlating many of the facts observed in the dyeing of textile fibres with mordant or adjective colouring matters. The tinctorial effects produced are due to the formation within the fibres of insoluble coloured salts or lakes which in general are characterised by the following properties: sparing solubility in aqueous solutions, exceptional shade and fastness of colours, resistance to chemical reagents, and an inhibition of the ordinary analytical reactions of the metallic bases implicated in the lake complex. By the use of a cobaltammine reagent, Drs. Morgan and Main Smith have shown that in three series of adjective dyes—the quinoneoxime dyes, the alizarin series, and the azosalicylic acid dyes—the formation of a complex lake is due to the presence in the adjective colouring matter of a characteristic radical—the so-called "chelate" group—which has the distinctive property of satisfying completely the chemical affinity of the metallic component of the lake. These researches are being extended to other natural and synthetic adjective colouring matters.

AT the end of the recent gliding week on the South Downs, the German duration records were broken by a Frenchman, M. Alex. Maneyrol, who stayed in the air 3 h. 22 m. The machine used in this feat was a Peyret Tandem Monoplane, and it was remarked at the time that this machine recalled the form of aeroplane constructed by S. P. Langley many years back. In a note issued by the Smithsonian Institution on November 28, 1922, reference is made to this vindication of Langley's design of a flying machine, and a short account is given of the history of the researches conducted by Langley. He began in 1887, and by 1892 had evolved a small "aerodrome" model. In May 1896 a model flew for 1½ minutes (a photograph of this flight accompanies the note). Work on a full-sized machine began in 1898, and was supported by the War Department, Board of Ordnance and Fortification, U.S.A. A machine was ready in 1903, but the trials were unsuccessful and hostile press criticism caused the withdrawal of official support. Langley died in 1906. It is claimed that the original machine, "overhauled but not materially changed," flew in 1914, and that "these flights proved conclusively the fact that Prof. Langley developed and built the first man-carrying aeroplane capable of sustained free flight." No reference is made to the recent controversy on this question of priority.

MAJ. W. F. BLAKE gives in *Discovery* for January a full account of the attempt to fly round the world made by Capt. N. Macmillan, Mr. G. Malins, and himself. Beginning their journey on May 24, 1922, his

party crossed to Marseilles, thence *via* Athens, Aboukir, Bagdad, Bandar Abbas, Quetta, Lahore, Agra, Cawnpore, reaching Calcutta on August 12. The passage over India was impeded by an unusually heavy monsoon. At Agra, Maj. Blake was struck down by appendicitis, and the other two members of the party on route to Rangoon were forced to descend in the Bay of Bengal, where they were fortunately rescued by Lieut.-Commander Canning, who had been sent from Chittagong to search for them. Maj. Blake, with the experience gained from their adventure, hopes to make a further attempt in 1923.

THE inaugural meeting of the Far Eastern Association of Tropical Medicine was held in Manila in 1908; it was followed in 1910 by the first congress at the same place. Subsequent meetings were held in Hong-kong, 1912, and Saigon, 1913. The fourth congress was held at Weltevreden, Java, in August 1921, and a proposal made on behalf of the Governments of the Straits Settlements and Federated Malay States, that the next congress of the association, in 1923, be held in Malaya, was accepted. Dr. A. E. Horn was chosen president for the forthcoming session; Drs. A. L. Hoops and R. Dowden were elected vice-presidents for the Straits Settlements and Federated Malay States respectively, and Dr. J. W. Scharff as honorary secretary for Malaya. The association, which is open to all recognised medical men, exists to promote the science and art of tropical medicine in the Far East. To this end, it provides opportunities for intercourse among medical men and endeavours to assist in the enlightenment of public opinion on problems of hygiene and particularly of the prevention of disease among the natives. The forthcoming meeting will be held on September 3-17, 1923. The first week of this period will be devoted to scientific discussions, and the following week to excursions to places of medical and sanitary interest throughout Malaya. The Governments of the Straits Settlements and Federated Malay States, recognising the important functions of this association, are contributing a considerable sum towards the expenses.

THE report of the eleventh ordinary meeting of the International Meteorological Committee, held in London, 1921, has recently been published by the Meteorological Office of the Air Ministry. It contains details of the several meetings of the committee and of the commissions for weather telegraphy, marine meteorology, aerial navigation, *réseau mondial*, and polar meteorology. A general account of the work of the International Meteorological Committee has already been published in NATURE (October 6, 1921, p. 194) shortly after the close of the eleventh ordinary meeting held in London in September 1921. The present report occupies 128 pages, more than one half of which consists of appendices giving detailed information of the several commissions held for reporting to the general meeting. Among the details of interest may be mentioned the recommendation that the meteorological stations in high latitudes, commenced in connexion with Amundsen's polar expedition, be continued during 1921 to 1925, and if possible permanently. Other points discussed are the unification of upper air data so that it might be possible to publish, within a few hours of the observations, a chart of upper air observations for the whole of Europe; the study of clouds from the point of view of aviation and the general application of meteorology to aerial navigation; and an endeavour to systematise the adoption of the "kilometre per hour" as the unit of wind velocity by all countries both for land and air. An effort was also made to standardise instruments for registering sunshine.

THE annual report of the Raffles Museum and Library, Singapore, for 1921 shows that, under the energetic direction of Major J. C. Moulton, these institutions make good progress. The number of outside helpers in Singapore and other parts of the world on whose services the museum can draw is a good sign. The formation of a Singapore Natural History Society, with headquarters at the museum, is recorded. Out of 240,000 visitors of various nationalities, 165,000 were Chinese.

MR. BAILEY WILLIS, in a popular paper on "The Geology of the Colorado River Basin with reference to Engineering Problems" (*Science*, August 18, 1922), discusses the boulder-bed in the floor of the Colorado cañon, and the difficulties of building a concrete dam on such a foundation. Work can be carried on between flood-times only, and hence it has been boldly suggested that, since the floods can shift the boulders, more boulders shall be quarried out of the jointed granite and given as playthings to the floods. The river is to be encouraged to construct its own dam to the satisfaction of the engineers who seek to utilise its power.

A WELCOME second edition has made its appearance of the admirable "Guide to the Elephants (Recent and Fossil) exhibited in the Department of Geology and Palæontology in the British Museum (Natural History)." As before, its preparation is the work of Dr. C. W. Andrews, whose name is sufficient guarantee of its excellence. It is slightly increased, as compared with the first edition, by additions to the text, chiefly in the opening paragraphs, and by a new figure. There are also numerous minor emendations, while useful sub-headings have been inserted. Economy has been appeased by issuing the pamphlet in paper covers instead of paper boards.

WE have received a copy of the third volume of Messrs. Baird and Tatlock's Standard Catalogue of Scientific Apparatus. This covers the more specialised apparatus useful in the biological sciences—anatomy, botany, zoology, pathology, agriculture, etc.—though physiology and biochemistry are dealt with in volume 2. The abundant illustrations make it a convenient and useful guide to most of the apparatus which is available, and in turning over the pages a scientific worker may get useful hints towards solving special problems of technique familiar in some department other than his own. Such catalogues do something at any rate towards bringing the different branches of biological inquiry together as well as in facilitating the daily work of the laboratory.

Our Astronomical Column.

NEW OBSERVATIONS OF JUPITER.—Mr. W. F. Denning informs us that Mr. Frank Sargent, of the University Observatory, Durham, observed Jupiter on the morning of December 24, and saw the hollow in which the great red spot is situated central at 19h. 13m. G.M.T., which corresponds to a longitude of 239°·6. Mr. Sargent considered this hollow in the great southern belt decidedly more shallow than formerly. The great red spot appeared to be shorter than at the last opposition, its length being estimated as only 22 degrees.

Following closely behind was the preceding end of the south tropical disturbance which made its transit at 20h. G.M.T. in longitude 268°. The rotation periods of these two objects during the last six months were:

Red Spot Hollow = 9h. 55m. 38s·1.
S. Tropical Disturbance = 9h. 55m. 29s·8.

These periods correspond very nearly with those derived during the earlier part of the year 1922.

BAADE'S COMET.—This comet was observed by Dr. W. H. Steavenson on December 20 and 22. He describes it as follows: "Magnitude 9 to 10, small, compact; diameter about 1′; best defined in position angle 165°, rather diffuse towards 345°; there was central condensation, but no well-defined nucleus."

The brightness is only falling off slowly, and the comet is still within reach of moderate instruments. The following ephemeris, by Mr. Johannsen, of Copenhagen, is very accurate. It is for Greenwich midnight:

	R.A.			N. Decl.
	h.	m.	s.	
Jan. 5.	22	55	22	19° 16′
,, 9.	23	4	30	18 46
,, 13.	23	13	30	18 18
,, 17.	23	22	22	17 54
,, 21.	23	31	6	17 31
,, 25.	23	39	43	17 11

The comet is crossing the lower portion of the square of Pegasus. It is desirable that observations should be continued as long as possible, in order to detect any deviation from parabolic motion.

BRITISH ASTRONOMICAL ASSOCIATION HANDBOOK FOR 1923.—Two years ago, when the well-known "Companion to the Observatory" was discontinued, the Council of the British Astronomical Association decided to bring out the Handbook to take its place (London: Eyre and Spottiswoode, Ltd. Price 2s. to non-members.) Its aim is to supplement, not to supersede the Nautical Almanac, from which little is reprinted except the physical ephemerides. The periods of visibility of the planets are shown graphically; details of important occultations, including four of Aldebaran, are given for 12 stations. Ephemerides are given for Vesta, Eros, and D'Arrest's Comet; it is hoped to extend this section further in future. The large-scale diagrams of the small stars near Uranus and Neptune will be useful for observers of these planets. Notes are included on telescopic objects, lists of tests, ephemerides of variables, and in particular the dates of maxima of 27 stars that attain naked-eye visibility. There are also definitions and an extended list of astronomical constants and elements, which will be slightly varied from year to year. There are thus few observers who will not find the book useful in their domes.

ATMOSPHERIC DISPERSION IN PARALLAX WORK.—One of the factors in the great improvement that has been effected in the photographic determination of stellar parallax has been the recognition that work must be limited to the neighbourhood of the meridian, where the effect of atmospheric dispersion is small. Messrs W. M. H. Greaves and C. Davidson have investigated the resulting correction to the parallax for stars of extreme spectral type in a paper read at R.A.S. November meeting. At 20 minutes of time from the meridian the correction for type B_0 is $-0''{\cdot}009$, and for type M $+0''{\cdot}005$. These are quantities that cannot be neglected nowadays, so the necessity is emphasised for working still closer to the meridian where possible.

The same difficulty is present in obtaining the solar parallax from photographs of Eros or other small planets, especially since the diurnal method necessarily involves considerable hour angles. The error can be diminished by using a visual refractor with a light filter, if the object is bright enough to permit of this.

INTERFEROMETER MEASURES OF DOUBLE STARS.—The *Astrophysical Journal* for July has a paper by Mr. Paul W. Merrill on this subject. Mr. Merrill continued the observations of Capella with the 100-in. telescope at Mt. Wilson, and gives the following orbit from his own and Anderson's measures: Period 104·022 days, $a = 0''{\cdot}0536$, distance = 126,630,000 km., parallax $= 0''{\cdot}0632$, masses 4·2 and 3·3 in terms of sun. He finds that the Greenwich measures in 1900 (on which considerable doubt has been cast) are fairly well represented on the supposition of a motion of the node of 0°·9 per annum; this motion is suggested by the interferometer measures themselves.

The duplicity of κ Ursæ Majoris was independently detected with the interferometer. The magnitude difference is much greater than in Capella, but does not exceed half a magnitude. When Aitken discovered its duplicity in 1907-8, the position-angle and distance were 283°·2, $0''{\cdot}21$; they are now 251°·3, $0''{\cdot}08$.

υ^2 Bootis was also examined, but the results were more doubtful; the method is obviously a very powerful one in cases where the magnitudes are not too unequal.

SOLAR PROMINENCE ACTIVITY.—Every half-year the Kodaikanal Observatory, India, issues a bulletin giving a summary of prominence observations during that period. The data for the first half of the present year in Bulletin No. lxx. have just been received. The mean daily areas and daily numbers of the prominences are few, as was to be expected from the cyclical nature of the phenomena, the respective figures being 3·17 (square minutes) and 11·05. Their distribution in latitude shows maxima in the belt 45°-50° in both hemispheres, and is very similar to that for the previous half-year; this indicates that a new cycle of activity has begun in the higher zones of prominences. The statistics give further the distribution of prominences east and west of the sun's axis, the activity of the metallic prominences, particulars of the displacements of lines observed in the spectra of the chromosphere and prominences, reversals and displacements of $H\alpha$ and D_3, and finally, areas and numbers of prominences projected on the disc as absorption markings. These valuable data are of great importance because they provide a complete record of the activity of the sun from a prominence point of view on a homogeneous system.

Research Items.

SUICIDE RATES.—The relation of suicide to climatic and racial factors, and to industrialism, occupation, urban conditions, age, and sex, etc., is the subject of an extensive statistical analysis by Dr. J. R. Miner (*American Journal of Hygiene*, Monographic Series, No. 2). It has long been recognised that the suicide rate is higher among the Nordic race than among Alpine or Mediterranean peoples. Mixed peoples usually have a higher rate than either of the pure races to which they belong. Foreigners in New York show a higher suicide rate than in the countries from which they came. The lowest rate is found in Ireland and the highest in Saxony, while the rate varies in different parts of France according to the racial composition of the population. Among Asiatic peoples, the Japanese and Chinese rates are high, while in India it is low (4·8 per 100,000). India appears to be the only country where female suicides exceed the male. The general trend of suicide rates has been upward during the last century, but the higher rates tend to become stabilised. A sharp decline took place during the war. Germany, France, Denmark and Sweden have high rates, Britain, Norway and the Netherlands low rates, as well as southern and eastern Europe. In the United States the rates are lowest in the south and highest in the west. The fundamental causes of these differences are found to be probably in (1) differences in the strength of the group spirit, (2) adverse economic conditions, (3) racial factors, (4) general health of the population.

REPRODUCTION IN THE LEODICIDÆ.—Prof. A. L. Treadwell's memoir on the Leodicidæ (Eunicidæ) of the West Indian Region (Dept. Marine Biol. Carnegie Instn., Washington, 131 pp., 9 pls., 467 text figs., 1921) gives a full systematic account and records in the text and in the coloured plates the character of the living coloration. Included in this family is *Leodice* (*Eunice*) *fucata*, which lives in crevices of the coral rocks, protruding the anterior end for feeding but not exposing the remainder of the body except at the breeding season. On the approach of the breeding season the body becomes much distended with eggs or with sperms and swarming occurs usually in coincidence with the last quarter of the June-July moon. During the night the worms protrude their posterior ends from the rocks and break them off at the junction between the sexual and non-sexual portion. The sexual portion swims to the surface and is found in large numbers on the surface at daybreak. Just at sunrise the thin body-wall bursts, the eggs and sperms are liberated, and fertilisation of the eggs occurs. Prof. Treadwell showed in 1914 that there is a measurable increase in the output of carbon dioxide by the egg as it approaches maturity, and he suggests that increased elimination of waste products into the body cavity of the worm may act as a stimulus to egg-laying.

DIGESTION OF WOOD BY THE SHIPWORM.—Dr. P. Bartsch's monograph of the American Shipworms (Bull. 122, U.S. Nat. Mus., 1922, 51 pp., 37 pls.) is restricted to the systematic aspect. He recognises in the family Teredidæ three genera—Bankia, divided into four sub-genera, with eight species; Bactronophorus, not yet reported in American waters; and Teredo, divided into seven sub-genera, with twenty-one species. Systematic descriptions of and keys to the species are given. Dr. Bartsch remarks that although the shipworm takes wood resulting from its boring operations into its alimentary canal, it is questionable whether the secretions of the digestive glands are capable of producing from the wood any soluble carbohydrate. Harington (*Biochem. Journ.* xv., 1921, pp. 736-741) investigated this point more than a year ago and, though he was not able to reach a definite conclusion, the balance of evidence was in favour of the view that Teredo has in its liver an enzyme capable of producing glucose from some constituent of wood, and hence it may be supposed that the wood is to some extent made use of as a source of nourishment.

AMERICAN MYCOLOGY.—The first part of volume 9 of the Annals of the Missouri Botanical Garden (February 1922) is completely filled with a revision by Prof. E. A. Burt of the North American species of Clavaria. This study will be of great value to American students of this group of fungi, and British mycologists will note with satisfaction that full use is made of the valuable study of the British species by Cotton and Wakefield in the Transactions of the British Mycological Society (1919). The author's discussion shows that plenty of work remains to be done by American mycologists, but probably this work with its full reference to American type specimens will provide the necessary stimulus as well as the basis from which to start. The illustrations, photographs of dried herbarium specimens, seem scarcely suitable for a work of this systematic character. In some cases, recognition may be facilitated by the photograph, in others it may well be misleading to unexperienced mycologists. Figures 90, 91, 92, and 94 might very well have been obtained from a single gathering of any one of the four species illustrated.

WET BULB TEMPERATURES AND THERMODYNAMICS.—In the memoirs of the Indian Meteorological Department, vol. xxiii. part 1, Dr. C. W. B. Normand, Imperial Meteorologist, discusses wet bulb temperatures and the thermodynamics of the air. In India in recent years the daily values and the monthly means of wet bulb temperatures have been published, since medical officers pay more attention to the wet than to the dry bulb readings, especially as to conditions liable to cause heat strokes. The aim of the paper is to create further interest in the actual wet bulb temperatures. Mathematical considerations are freely introduced, and the discussion opens up the subject to wider considerations. At the fortnightly meeting held at the Meteorological Office on October 30, the paper by Dr. Normand was taken for discussion, and the subject was opened by the author, who is now in England. A summary of the discussion at the Meteorological Office is given in the *Meteorological Magazine* for November. It was brought out that the term "wet bulb temperature" in the paper is ambiguous, and it was suggested that it seems better to use the term "adiabatic saturation temperature."

METEOROLOGY IN INDIA.—A report on the administration of the Meteorological Department of the Government of India in 1921–22 has just been received. It is drawn up by Dr. Gilbert T. Walker, Director-General of Observatories to the Indian Government. After special investigation Stevenson's thermometer screens, commonly used in Great Britain, are to replace the large open-sided shade hitherto used in India for the exposure of thermometers. This will bring India into line with our home observations, and will effect a very great saving of expense when new screens are required. The English screen

is only about one-sixteenth of the price of the Indian screen hitherto used. Much valuable data on the upper wind currents have been recently published and other upper air data are ready for publication. Considerable demand is being made for upper air results over India and the report regrets the inability to do all that is required for want of funds. In the British Isles the staff of workers has been immensely increased and without doubt considerable increase of the staff in India will have to be faced, although it will mean added expense. A graph showing the growth in activity and cost for the last 15 years is given at the end of the report. For want of funds much useful work has been discontinued. The stations over India from which detailed observations are received now number 281, and these have to be supplied with instruments and inspected periodically. Observations are secured from vessels by wireless, as well as from the ordinary logs, over the neighbouring seas. Seismological observations are recorded at several stations and the data are supplied to the British Association. For rainfall over India, there are now 2928 stations from which observations are received.

THE NEW FLIGHT COMPASS.—The United States Air Service has set itself the task of putting the navigation of the air on as trustworthy a basis as that of water, and as part of its programme has asked the Bureau of Standards to investigate the possibilities of the earth inductor type of compass. As a result, a form of instrument has been devised which has proved more satisfactory than any previously in use in the Air Service. A memoir describing the instrument was presented in 1921 to the American Philosophical Society by Messrs. P. R. Heyl and L. J. Briggs, and was awarded the Magellanic premium. It is now reproduced in part 1 of volume 41 of the Proceedings of the Society. An armature driven about a vertical axis by a cup propeller has four carbon brushes set at right angles to each other in contact with its commutator, and capable of being set so that when the aeroplane is flying in a fixed direction, one pair of brushes gives a maximum and the other pair zero electromotive force. The two pairs of brushes are connected to four equally spaced points of a closed electric circuit and a pointer galvanometer connected to two points opposite each other on the circuit. The diameter for which the galvanometer gives zero deflection is determined by the course of the aeroplane.

BURNING HEAVY FUEL-OIL.—Some of the technical difficulties encountered in burning heavy fuel-oil in Diesel engines and other types of heavy-oil engines were discussed by Mr. Harold Moore in a paper read by him at the North-East Coast Institution of Engineers and Shipbuilders, Newcastle, early in December. Ignition trouble, difficulties in burning oil after ignition has taken place, and the problems raised by the presence of small quantities of impurities, were the main factors dealt with as affecting the utilisation of heavy fuel. With regard to ignition trouble, a great deal depends on the range of ignition temperatures possible with varying types of oil-fuel; in Diesel and cold-starting engines, ignition takes place when the heat of compression exceeds the spontaneous ignition temperature of the oil, and it is customary to adjust the compression so as to ensure regular ignition of whatever class of fuel is burnt. The utilisation of various petroleum and coal-tar oils necessitates repeated adjustments being made, and these, under changing conditions of low and high load running, atmosphere, etc., have to be considered carefully both theoretically and practically. Pilot ignition gears, which to a large extent overcome initial difficulties of firing, are now installed on most Diesel and cold-starting engines. After ignition has taken place, the smooth burning of the oil depends primarily on its complete combustion before the exhaust valve opens, and on the rate of burning and influence of the various substances in the fuel. Such substances include the bituminous bodies present in petroleum, hard and soft asphaltum, waxes, and in the case of coal-tar oils (more often employed on the continent than in this country), naphthalene and anthracine. Finally the effects of water, sand, and iron rust, the commonest impurities in oil-fuel, constitute not unimportant factors to be reckoned with. Such impurities are best removed by the employment of high-speed centrifuges.

MAGNETIC OBSERVATIONS AT BATAVIA.—Volume 40 of the Observations made at the Royal Magnetical and Meteorological Observatory at Batavia contains the observations of the year 1917. The preface, however, brings the history of the observatory down to February 1922. From it we learn of the retirement of the well-known director, Dr. W. van Bemmelen, who has been succeeded by Dr. Braak. In addition to the usual meteorological tables, the publication contains some special results of interest, including the results of a 7-year comparison of ordinary thermometers in the thermometer shed and ventilated Assmann thermometers outside. The differences are substantial. The magnetic results are very complete, two magnetographs being in constant operation. The tables of hourly values refer to three rectangular components of force, the horizontal components being in and perpendicular to the astronomical meridian, which is there nearly coincident with the magnetic. An interesting chart shows the departures of the three rectangular components from their mean yearly values. These departures are calculated for 1 h., 7 h., 13 h., and 19 h. G.M.T. of every day, the value assigned to each hour being a mean from 24 hours centering at that hour. The great predominance of disturbance in the north-south component is effectively shown.

PHOTOGRAPHIC SENSITISERS AND DESENSITISERS.—Prof. Rudolfo Namias describes some of his remarkable experiences with these reagents in "The Process Year-Book," vol. xxv., 1923. He agrees with Dr. Luppo Cramer that pinaflavol, the most recently introduced colour sensitiser, is unique in its property of sensitising for the well-known gap in the greenish-blue, and that it and pinacyanol give a "very high increase of general sensitiveness." He finds that pinacyanol may be used in a solution fifty times diluted as compared with the concentration generally advised (finally equal to one part of solid in five millions) and that the spectrographic tests show that this enormous dilution makes no difference in its effect. He has discovered that desensitisers are more important than they were at first thought to be. By getting rid of the sensitiveness of the plate they avoid the formation of the development fog always produced when development is continued to bring out the weak detail which, however, is generally buried by it. By making this detail available we get a practical increase of sensitiveness, though the advantage is restricted, so far as is known, to the use of safranine, and of hydroquinone and alkaline bromide in the developer. The increase of general sensitiveness and the elimination of development fog enable one to use slow plates with their much finer grain, and so, without the practical sacrifice of sensitiveness, to get a considerable gain in resolving power.

The Wegener Hypothesis.

DISCUSSION AT THE BRITISH ASSOCIATION, HULL.

ON Monday, September 11, the meeting room of the Geological Section of the British Association was the theatre of a lively but inconclusive discussion on the Wegener hypothesis of the origin of the continents. This hypothesis, which is a development of the well-established theory of isostasy, regards the continental masses as cakes of light siliceous material floating on a heavier basaltic, fluid or viscid, substratum, which in its turn reaches the surface in a solidified form on the floors of the oceans. The continents, which are thus movable, are supposed in Carboniferous times to have formed a single mass, and to have split up by rift-valley formation and started floating apart in late Cretaceous or early Tertiary times. The mountain ranges fringing the Pacific are supposed to have been produced along those margins of the continents which are or have been, in virtue of their motion, impinging on the hard oceanic crust, the belts of thick sedimentation along the continental shelves localising the folding.

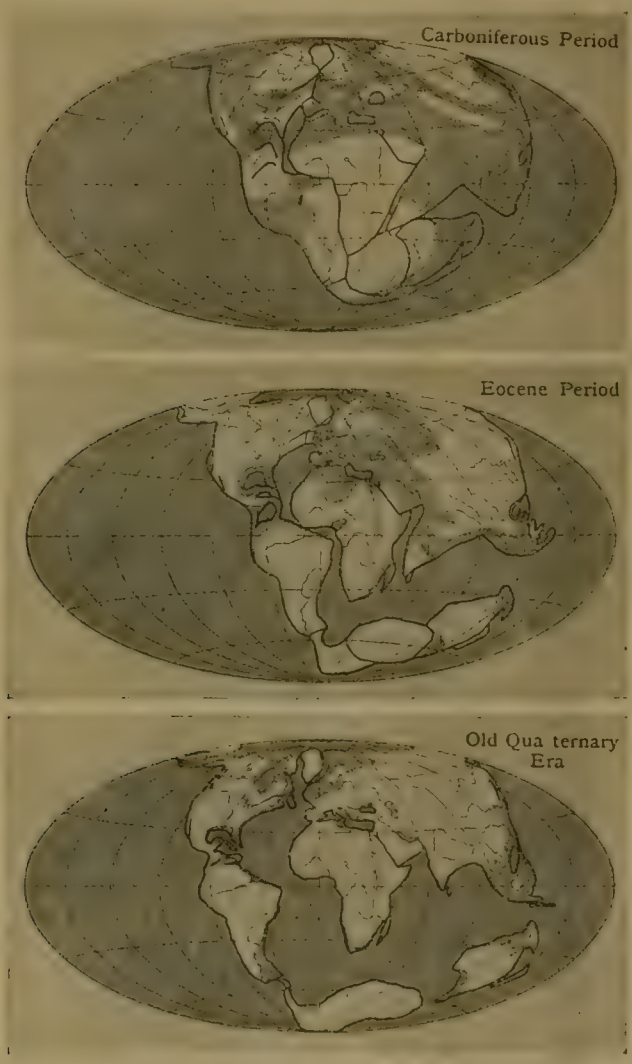

FIG. 1.—The world in the Carboniferous and Eocene periods and Old Quaternary era according to the displacement theory. White denotes land, dots shallow water, cross-hatching deep sea. From *Discovery*, May 1922, p. 116, by the courtesy of the publishers.

The union of the continental masses in former geological times explains many peculiarities in the distribution of life both past and present. It also affords an easy explanation of the hitherto unsolved problem of the Permo-Carboniferous glaciation, by supposing the pole to have been located in South Africa and the other glaciated parts of Gondwanaland to have been grouped around. When a reconstruction of this sort is made it is found that the main Carboniferous coalfields of the world lay, at the time of their formation, within the tropics.

The discussion brought forth a great diversity of opinion regarding the validity of the hypothesis, almost the only point on which there seemed to be any general agreement being an unwillingness to admit that the birth of the North Atlantic could have occurred at so late a date as the Quaternary. Proceedings were opened by the reading of a discourse by Dr. J. W. Evans, who was unfortunately unable to be present. Dr. Evans gave an outline of some of the leading features of the theory and emphasised the well-known similarity of the geological formations on opposite sides of the oceans. He, however, questioned Dr. Wegener's estimates of the thickness of the crust whether continental or oceanic, and considered that the latter, being probably as strong as the continental crust, would inhibit the continental drift. He dealt more particularly with the supposed recent variations of relative longitude and with the precautions which would have to be taken in the case of an attempt to repeat the observations.

Prof. H. H. Turner stated that the only piece of astronomical evidence supporting Wegener's hypothesis, and worthy of serious consideration, was the apparent westerly drift of Greenland. He was inclined to regard the longitude observations made up to the present as so much waste paper, but considered that the magnitude of the discrepancies between the Greenland observations of the years 1870 and 1907, which indicated a westerly drift relatively to Europe of 1200 metres, made a good case for repeating the observations to-day.

Mr. W. B. Wright pointed out that a critical comparison of the geological formations on the two sides of the North Atlantic shows on the whole a very remarkable correspondence, both stratigraphical and palæontological, from the Archæan to the Cretaceous, and in particular brings to light certain facts even more strikingly indicative of a former *rapprochement* between the two continents than any pointed out by Wegener.

The recurrence in America on opposite sides of the old Appalachia of the two facies of the European Cambrian and early Ordovician, which are here separated by the Caledonian chain, is perhaps the most striking, the lithological and faunal characters and the sequence of transgression and recession, different on either side of the chain, being reproduced with remarkable precision. Again, the continental and marine facies of the Devonian are separated in both countries by boundaries which become conterminous on the Wegener reconstruction.

Prof. Coleman, of Toronto, considered that the similarity in the Archæan formations on the two sides of the Atlantic, cited by Mr. Wright, meant very little, as the Archæan was a universal formation. He also raised the question of the meteorological

conditions of the supposed compacted continent of Gondwanaland, which he thought must necessarily have been a desert and therefore could not have nourished an ice sheet.

Prof. Sollas confessed himself attracted by the theory but doubtful as to proofs. He was not greatly impressed by arguments based on the similarity of the geological formations on the opposite sides of the oceans, the most remarkable of which was perhaps that cited by Mr. Wright. A certain uniformity is to be expected in rocks derived from the same Archæan base. The explanation on the whole was out of proportion to the points of correspondence cited.

Dr. Harold Jeffreys stated that the rotational force which could be invoked to explain the movements of the continents was very small and quite insufficient to produce the crumpling up of the Pacific ranges. The ocean floors also presented a difficulty, for, being composed of basaltic rock, they would be less radioactive and therefore stronger than the continental crust. The withdrawal of India northward and its gathering up into the Himalayan folds were moreover not easily accounted for.

Prof. Gilligan said that, as the great piles of Palæozoic sediments in Europe and America reached their maximum thickness on the borders of the Atlantic, it seemed necessary to assume the presence of a continent occupying the northern part of the ocean. The time-honoured conception that the earth shows a tendency towards a tetrahedral form was also in conflict with this new hypothesis.

Dr. G. C. Simpson thought the theory was a wonderful one from the meteorological point of view, as it explained the marked changes of climate given by the geological record and in particular the excentric position of the Quaternary ice-sheets with reference to the pole.

Prof. Marshall, of Wanganui, New Zealand, pointed out that the movement of that country was to the east and not to the west. Speaking from personal knowledge of a number of the Pacific Islands and referring to the evidence they afforded as to the composition of the floor of the ocean, he said it was a mistake to suppose that the igneous rocks exposed in these islands were entirely basaltic. Alkaline rocks were also represented, but, so far as he was aware, siliceous rocks of continental type were unknown.

Dr. F. E. Wright spoke briefly, and Prof. Boswell referred to the forthcoming English edition of Dr. Wegener's book as affording an easy means of becoming acquainted with the leading features of the subject.

The president, Prof. Kendall, in closing the discussion said he had many years ago examined the question of a land connexion across the Atlantic, especially in its bearing upon the distribution of fishes and reptiles. The practical identity of the Old Red fish faunas of the Orkneys and N. America seemed to show a very close connexion, and the similarity extends to the Carboniferous. Divergence, especially in the reptiles, is marked in the Trias and probably complete throughout the Jurassic. Unfortunately the reptiles require two barriers, one of land to stop the migration of the marine forms, and one of sea to inhibit that of the land forms. The evidence adduced by Martin Duncan and marshalled by Gregory proved a connexion between Europe and America during the Oligocene. He had long ago found it necessary to abandon a belief in the absolute permanence of ocean-basins.

The discussion as a whole was interesting as bringing out the extreme divergences of opinion produced by viewing the hypothesis from different aspects, astronomical, physical, meteorological, and biological, but it becomes very apparent that the surest test of its validity lies in the domain of geology.

W. B. WRIGHT.

The National Research Council of America.

THE National Research Council of the United States corresponds to the Department of Scientific and Industrial Research in this country. It owes its being, as does our organisation, to the very urgent need, which the war made patent to governments, of an organised and systematic attempt to foster scientific research, to extend its industrial applications and, by co-operation and co-ordination, to do this on a national scale. The sixth annual report of the National Research Council, for the period ending June 30, 1921, shows clearly the extent to which this organisation has been carried in the United States. There are divisions based on political classification, *e.g.* Federal, foreign and States relations; on functional classification, *e.g.* educational relations, research extension and information service; and, finally, on a scientific and technological classification, *e.g.* physical sciences, engineering, chemistry and chemical technology, geology and geography, medical sciences, biology and agriculture, anthropology and psychology.

A popular chemical exhibit "to show the American people what the chemist has done and may do for them," prepared by the Chemical Warfare Service of the United States Army, was held in Washington, and arrangements have been made to install it as a permanent exhibit in the United States National Museum.

The division of educational relations has given special attention to the study of the detection and encouragement of students of superior ability, and is co-operating in this investigation with the division of anthropology and psychology.

Among the projects of the division of research extension may be mentioned the following: An underwriting fund of 200,000 dollars is to be raised for the compilation of critical tables of physical and chemical constants. Measures are afoot for the establishment of a Crop Protection Institute; an Alloys Research Association; a school for tanning to be affiliated to an established university; a Textile Research Institute; and a Horological Institute of America, which will be concerned primarily with the scientific phases of time keeping with special reference to the mechanical devices necessary.

The research information service has for its purpose "to promote scientific and industrial research in this country through the operation of an active exchange for all kinds of scientific and technological knowledge." It prepared for publication Bulletin No. 9, Funds Available in 1920 in the United States of America for the Encouragement of Scientific Research, giving an account of medals, prizes, grants and research scholarships and fellowships amounting in value to approximately 36,000,000 dollars annually. In addition to research in personal records the service has a catalogue of 20,000 chemists and mining engineers, and a file of current investigations.

From the division of engineering a report embodying the results of the investigations on fatigue phenomena of metals will be published shortly. The results indicate that a rise of temperature test may

furnish a trustworthy accelerated test for fatigue resistance. It is stated that "this report contains the most valuable and complete information ever published on this subject." We shall await its appearance with much interest.

Owing to the very sudden increase in the destruction of marine piling in San Francisco Bay resulting from the attack of marine borers, which amounted in value to about 15,000,000 dollars in the last year or two, a marine laboratory has been established in San Francisco Bay and the National Research Council has taken measures for undertaking co-ordinated investigations on the problem. The report states: "This is one of the most important problems presented to the National Research Council since its organisation and one of the best illustrations of the important service which can be rendered by a national body of this sort. It is also an excellent illustration of the need for co-operation between the scientific and engineering groups."

The committee on ceramic research has selected the following four subjects to receive early attention: (1) A study of the elements which determine the plastic nature of clay; (2) a critical examination of certain methods used in silicate analysis; (3) a study of American pot clays and their proper compounding for the production of refractories used in the glass industry; (4) a study of the relationship between crazing and the expansion coefficients of bodies and glazes.

Enough has been indicated of the character of this sixth annual report of the National Research Council to convince, perhaps, even the warmest exponent of the theory of science for science's sake and of the inalienable right of the scientific spirit to go whither it will, that there is a vast field of scientific research meet for organised co-operation on national lines. J. W. W.

International Contributions to Mendelism.

THE Dutch journal *Genetica*, under the editorship of Dr. Lotsy and Dr. Sirks, has published an excellent international number as a Mendel Memorial in connexion with the recent centenary celebrations in Brünn and Vienna. In a long and carefully written article, Prof. V. Häcker (Halle) reviews the present state of knowledge of Mendelian inheritance, especially as regards cytological interpretation and other aspects of general interest. Such a cautious and well-informed statement is most valuable at the present time. Dr. E. Fischer (Zürich) describes his large series of experiments in breeding the Silver-washed Fritillary (*Argynnis paphia*) and its dimorphic female, the well-known var. *valesina*. It used to be thought difficult to get such creatures to breed in confinement, but Dr. Fischer, following a technique which he describes, has raised several thousands as the result of various matings. Prof. R. Goldschmidt (Berlin) contributes an analysis, and suggests a factorial scheme which fits the numbers fairly well. There is a dominant *valesina* factor, V, which is not sex-linked, and the combinations VV, V*v*, *vv* are possible both in males and females. Since, however, the males are all *paphia* alike, their genetic constitution can be decided only by experimental breeding. We are still as far as ever from understanding how it comes to pass that the males are thus uniform, though they may contain even two doses of the element which in a single dose suffices to give the dominant character to the female, a difficulty which has puzzled geneticists very long. There are many parallel examples in butterflies of di- and polymorphic females, though nothing analogous is ever seen in the males. The cytological scheme which so successfully represents the observed facts in colour-blindness and similar examples here apparently fails, and the special interpretations offered by Goldschmidt, though suggestive, are scarcely more than a restatement of the difficulty.

Prof. Ghigi (Bologna) discusses the origin of domesticated poultry, especially fowls and pigeons, in the light of his breeding experiments. He leans to the conclusion, which other evolutionists have also reached, that it is most difficult to suppose, as Darwin did, that the various breeds of fowls are derived simply from *Gallus bankiva*, or the pigeons collectively from the rock-dove. The plausible suggestion is here made that the heavy breeds of fowls, which constitute the main problem, may have come from some partially flightless island form, taken bodily into domestication, since nothing of the sort now survives in a wild state. Some of the pigeons, he thinks, may be derived from crosses with *Columba leuconota*, which when bred with tame pigeons gives, as he found, at least fertile males. The effect of all these appeals to multiple origins, necessary as they now appear to be, is to weaken confidence in the classical deductions as to unlimited possibilities of variation under domestication apart from cross-breeding.

Other interesting papers are those of Prof. J. L. Frateur (Louvain) on compound characters, M. A. Meunissier (Paris) on the 3-podded and other varieties of peas, and Dr. Winge (Copenhagen) on some curious and complex phenomena in Drosophila, which favour the hypothesis already entertained by several biologists that mutation may sometimes be the consequence of a rare cross-over. Dr. Sirks (Wageningen) recounts his experiments with a new subspecies of *Linaria vulgaris*, giving a mixed F_1 generation in crosses with the wild type, an unexpected result which may be variously interpreted. A remarkable experiment is also described by Prof. J. Schaxel (Jena), who succeeded in grafting together limb-buds of the coloured and the white forms of Axolotl, producing limbs compounded of both elements so intimately associated that the name "Chimæra" may be applied to them, on the analogy of Winkler's famous graft-hybrids made between the tomato and *Solanum nigrum*.

This collection of memoirs reaches an unusually high level. All contain material of permanent value.

The Oldebroek Explosion of October 28, 1922.

IN NATURE of November 4, p. 619, a preliminary note appeared on the great explosion at Oldebroek. It is now possible to discuss more fully the results obtained.

About 140 reports were received from observers in the British Isles. Of these, nearly one-third stated that despite careful listening they heard no sound that appeared to be due to the explosion.

When the distribution of the positive and negative reports is studied, the most notable feature is the entire absence of positive reports from the greater part of the Midlands of England. With regard to Europe generally, it appears that the sound was reported so far off as 850 km. to E.S.E., 600 km. to S. and 700 km. to N.W. of Oldebroek, whereas no single trustworthy observation was reported in a zone

between the limits of 100 and about 180 or 200 km. radius. Confirmation of the existence of a "Silent Region" was therefore once more obtained. Also, the times which the sound waves took to reach various distances are in most cases longer than they would be for normal propagation through the surface air.

The accuracy of the time standard of the average non-scientific observer is not likely to be high, but when the British observations are classified with reference to apparent velocities of propagation, there appears to be some evidence that these tend to group themselves about points corresponding to velocities of 257, 335, 370, and 508 metres per second. The second group corresponds very closely to propagation through the surface layers of air, due allowance being made for temperature and wind. In view of the uncertainty as to the accuracy of the observed times, it is doubtful whether the observations of the third group are to be regarded as truly distinct from those of the second, but it is just possible that this velocity is to be explained by the assistance of a strong north-easterly wind, and, though there is no actual measurement, it is not improbable that such a wind may have existed somewhere about the three- or four-kilometre level. At a height of one kilometre the mean wind over south-east England was north-easterly 15 m/s, and at a height of two kilometres E.N.E. about the same velocity. A *ballon sonde* reaching 9 km. indicated a resultant drift for the whole trajectory from about N.N.W., and a cirrus cloud observation obtained in Holland indicated an apparent velocity equivalent to 33 m/s from W.N.W. at a height of 10 km.

Of special interest are the first and fourth groups with velocities centring at 257 and 508 m/s respectively. Five of the seven observations indicating the latter velocity were made at very considerable distances from Oldebroek, namely at Newcastle, Bolton-le-Moors, Skipton-in-Craven, Northallerton, and Guernsey. Prof. E. van Everdingen is of opinion that such observations and the proven existence of the "Silent Region" afford very strong evidence of the co-operation of the hydrogen atmosphere. The view that the appearance of silent regions is to be ascribed to a change in the constitution of the atmosphere at great heights was put forward by Von dem Borne in 1910. Making certain assumptions as to the constitution at great heights, he calculated that the shortest possible distance at which sound rays, curved back by this high atmosphere, could reach the surface was 114 km., the ray becoming horizontal at a height of 75 km. Actually no case of so short a distance has yet been found. In 1915 van Everdingen, taking Wegener's hypothesis as to the occurrence of geocoronium in the atmosphere and his percentage values as to constitution, showed that it gave no better a result. On testing various hypotheses, the best results appeared to indicate a percentage of hydrogen at surface level of 0·0001.

In addition to the observations discussed above collectively, certain special observations were made in this country. The Acoustical Research Section of the Signals Experimental Establishment contributed most valuable records obtained by means of hot wire microphones at Woolwich and at Biggin Hill, Kent. These were described and discussed in detail by Major W. S. Tucker in a paper to the Royal Society of Arts on November 29. In the case of the Biggin Hill record he attributes the first effect (indicating a velocity of nearly four times that of sound in air) to propagation through the water and the ground.

At Eskdalemuir Observatory at 17 h. 29 m. G.M.T. a small upward movement of about one-thirtieth of a millibar on the microbarograph record was followed about 13 minutes later by an approximately equal one in the opposite direction. On the traces of the other instruments, including the seismographs, no evidence of an explosion effect is to be found. Mr. J. J. Shaw (West Bromwich) could also find no evidence on his seismograms, but stated that at the critical time many thousands of pedestrians and heavy vehicular traffic (the returning crowd from a football match) were passing his house.

The collected observations of the various European countries are now being investigated by Prof. van Everdingen of the Dutch Meteorological Service.

University and Educational Intelligence.

AMONG University Extension agencies the Summer School plays an increasingly important part. This year eleven universities and university colleges in Great Britain were responsible for at least fifteen summer schools, not counting those organised by joint committees for tutorial classes in connexion with the Workers' Educational Association. In the United States, summer courses are provided in numbers and on a scale far in excess of anything that has been attempted elsewhere. The Bureau of Education, Washington, has published a Bulletin on the subject (1922, No. 31) in which are shown the student enrolments in last year's summer schools of the twenty-seven universities and colleges which sent representatives to the meeting of the Association of Summer School Directors. The largest were: Columbia 11,809, Chicago 6458, California 6176, Wisconsin 4547. Fourteen other institutions had enrolments exceeding 1000 each. On the other hand, many of the best known, including Yale, Princeton, Vassar, and Brown, do not receive summer students: Yale experimented with the system for three years and then gave it up. Some of the most conservative colleges, while not undertaking summer schools of the ordinary type, have opened their doors in the summer for conferences and for special classes designed to establish contact with industrial workers. Many hesitate, as do universities in this country, to increase their commitments in this direction for fear of financial difficulties. State universities regard the matter in a different light, and find that this and other forms of extension work help to justify in the eyes of the taxpayers their large demands on the public purse. In general the courses are devoted principally to the liberal arts and sciences and to education, but some schools of law, medicine and dentistry offer courses which count for their degrees, and in a few institutions engineering and architecture courses are provided.

FROM the Royal Technical College, Glasgow, we have received a copy of their annual report on the work of the session 1921–22. Owing to the cessation of special classes held at the request of the Ministry of Labour under their "Interrupted Apprenticeships" Scheme, the number of students was slightly lower than in 1920–21, but compared with 1913–14 the year's enrolment shows an increase of 150 per cent. The research work carried on in the college is extending rapidly in volume and importance, especially in chemistry, metallurgy, and engineering. Much of it is undertaken at the instance of industrial research associations by the associations' own workers under the supervision and guidance of the professors concerned. The course for the diploma in chemistry, recently extended from three to four years, includes in its final year three months devoted to experimental inquiry, on which a thesis is required to be written. This plan has been an unqualified success, the report says, from an educational point of view, and some of the theses presented last year were of such intrinsic

value as to warrant publication. In more than a hundred centres in the surrounding counties affiliated continuation classes in science and technology were conducted by education authorities: nearly all evening students entering the college, except those from a considerable distance, present qualifications gained in such affiliated classes. The school of pharmacy is now thoroughly established, and several students are preparing for the B.Sc. degree in pharmacy of the University of Glasgow.

RECENT developments in the Swedish national school system are described in an article by Prof. Hänninger of the Landskrona Training College in the November number of *School Life*—an official journal of the United States Bureau of Education. In 1919 the Government prescribed for use in the folk-schools a new instruction plan, the outstanding feature of which is "home and community study," involving lessons based on direct observation of the environment of home and school and linking the observed facts with geography, nature-study, history, drawing, and sloyd. About the same time were established two-year continuation schools with a total of 360 hours of instruction, directed in the main on practical lines, and including citizenship and the mother-tongue, and either a craft or natural history, sloyd, and horticulture. These schools are to be obligatory after 1924. Apprentice schools with two-year curricula, for which the continuation schools serve as a preparation, may be made compulsory at the option of the local community. In the apprentice schools the instruction comprises 6 to 12 hours per week during 8 or 9 months of the year. Beyond it is an optional crafts school with a one-year course. In a report just issued by a Grand School Commission proposals are made for substituting for the existing dual system (folk-school and *realskola*) a common foundation school to be attended by children of all classes for six years, leading to a middle school with a four-year course, to be followed by a three-year "gymnasium."

HIGHWAY Engineering and Highway Transport Education problems were discussed at a conference held at Washington on October 26-28, under the auspices of the United States Highway Education Board. Between 1910 and 1922 the number of motor vehicles increased 2000 per cent. (to ten and a half millions), while the increase in funds for road building was only 400 per cent. Neither highway construction nor highway transport education have kept pace with the stupendous increase in automobile traffic. The trend in the colleges at present is towards a system whereby certain fundamental courses covering about 5 semester hours in highway engineering are required of all civil engineering students, while an equal amount of optional supplementary highway instruction in the subject is offered for intending specialists.

IT is announced in the *British Medical Journal* that the University of Paris has received two gifts of 100,000 francs each from Madame Edouard Nathan. The first of these is to be applied to the improvement of the scientific laboratories of the University, and to the promotion of research work. The second is to be set apart for the purpose of making loans to impecunious students of the University to enable them to continue their studies.

THE *Chemiker Zeitung* of October 28 reports that Prof. Pfeiffer, of the Technische Hochschule, Karlsruhe, has been appointed Director of the "Josefine und Eduard von Portheim-Stiftung für Wissenschaft und Kunst" in Heidelberg, and will direct the Chemical Research Institute of this Fund.

Societies and Academies.

LONDON.

Physical Society, December 8.—Dr. Alexander Russell, in the chair.—G. **Shearer**: The relation between molecular and crystal symmetry as shown by X-ray crystal analysis. By X-ray analysis the number of molecules associated with the unit cell is determined. The symmetry number for each of the 32 crystal classes is shown to mean the minimum number of asymmetric molecules necessary in the unit cell to satisfy the symmetry conditions. The symmetry number is the actual number of molecules in the cell when the molecule is asymmetric; if the molecule possesses symmetry, this symmetry appears also in the crystal, and the number of molecules in the unit cell is obtained by dividing the symmetry number of the crystal by the symmetry number of the molecule.—E. A. **Owen** and G. D. **Preston**: Modification of the powder method of determining the structure of metal crystals. Plates of aluminium, iron, copper, lead, and magnesium have been examined by means of the Bragg X-ray spectrometer, employing radiation direct from a molybdenum anti-cathode. The maxima in the spectra are sufficiently intense to measure with accuracy, and the crystalline structure of the materials examined are readily determined.—A. B. **Wood**: The cathode ray oscillograph. The instrument is of the low-voltage type, in which a hot cathode is employed as a source of the electron current. This low-voltage type of oscillograph is much more sensitive than the high-voltage cold-cathode type of M. Dufour. There are various methods of focussing the cathode-ray stream, and it has been proposed to have an external (*i.e.* outside the vacuum) photographic film. Ordinary gelatin-coated roll films or plates are unsuitable, owing to the marked absorption of the cathode-rays by the gelatin. The best results have been obtained with Schumann plates containing calcium tungstate. This material phosphoresces with a light rich in ultra-violet, and consequently the secondary luminous effect on the Schumann plate is very great. Mechanical, electrostatic, and electromagnetic methods are described for generating a time-axis on the records.—R. **Webb**: A low-voltage cathode ray oscillograph. The instrument is designed to work at 300 volts. The cathode consists of a hot platinum filament coated with certain oxides, and formed into a circle coaxial with the path of the rays. It is protected from bombardment by positive rays, which would disintegrate it, by a screen in which is cut a circular hole slightly less in diameter than the filament. It has a life of about 200 hours. The anode is a platinum tube through which the rays pass. The deflecting fields are electrostatic, and are provided by two pairs of plates at right angles. The bulb is in the form of a conical flask, the cathode being at the narrow end so that the rays impinge on the flat bottom, which is coated inside with fluorescent matter. The luminous trace of the rays can be seen from outside through the bottom of the flask.

Royal Meteorological Society, December 20.—Dr. C. Chree, president, in the chair.—C. J. P. **Cave** and R. A. Watson **Watt**: The study of radiotelegraphic atmospherics in relation to meteorology. Results obtained in 1915, at the Meteorological Office Radio Station, Aldershot. Radiotelegraphic direction finding on atmospherics was introduced as a means of locating thunderstorms, and successful observations were made, with the co-operation of the Admiralty coast stations, on storms as near as five miles to an observing station, and on other storms 1000 miles distant. The first thunderstorm thus located, and

confirmed by subsequent meteorological reports, occurred in the south of Ireland on July 24, 1916, at a distance of 280 miles from the most distant station participating in its detection. A storm was traced across the Bay of Biscay and Southern France, a thunderstorm at Venice was located by two stations a thousand miles away, and a storm five miles from Aldershot was followed by the direction finder there, the bearings given being in complete agreement with the bearing of the audible thunder and the visible storm.—C. J. P. **Cave**: Winter thunderstorms in the British Islands. During the first three months of the years 1916, 1917, 1918, and 1920, the number of storms occurring in the winter months was very remarkable, there having been storms somewhere in the region on more than 40 per cent. of the days. Some of the storms were very widespread. They seem to have been connected with the occurrence of masses of air at widely different temperatures in close proximity. Thunderstorms are caused, it is suggested, (1) by the heating of the lower layers of the atmosphere, (2) by the cooling of the upper layers, (3) by a warm current of air rising over a cold one, (4) by cold air undercutting warm air.—D. E. **Row**: Forecasting sky-types. The type of pressure distribution as shown by a map or suggested by the "Further outlook" of the Meteorological Office, and the part of it which is likely to affect the locality concerned, is used, and local indications are considered. For example: Cirrus types followed by cumulus forms are to be expected during the passages of depressions, or even where overlapping occurs between an anticyclone and a depression. Indefinite areas of low or medium pressure often give very composite skies, thus yielding striking cloudscapes in which a large variety of cloud types is featured simultaneously.

DUBLIN.

Royal Irish Academy, December 11.—Prof. Sydney Young, president, in the chair.—J. J. **Nolan**: Ionic mobilities in air and hydrogen. The composite nature of ordinary ionisation in air is demonstrated by a third method. The ionisation in hydrogen is examined by the Rutherford-Franck method. The results obtained are similar to those already found for air and are, in general, confirmatory of the work of Haines. The ionisation is more complex than Haines's work would indicate, and a high degree of purity or drying is not necessary to bring out this feature. Criticisms by Blackwood are considered.

PARIS.

Academy of Sciences, December 11.—M. Émile Bertin in the chair.—Pierre **Termier**: The structure of the eastern Alps: relations of the Dinarides and the Alps.—A. **Rateau**: Pressures and specific gravities of air in a normal atmosphere.—M. H. Vincent was elected a member of the section of medicine and surgery in the place of the late M. A. Laveran.—Gaston **Julia**: Rational substitutions with two variables.—Maurice **Lecat**: The development of determinants as a function of determinants with axial empty spaces.—Lucien **Mouren**: New nomograms with aligned points applicable, in particular, to problems of navigation and their mechanical realisation.—M. Amoroso **Costa**: Concerning a note of M. Borel.—Mlle. O. **Jasse**: The Comas Sola planet of November 26, 1922: its identity with (629) Bernardina.—J. **Guillaume**: Observations of the sun, made at the Lyons Observatory during the second quarter of 1922. Observations were possible on 80 days in this quarter; the results are summarised in three tables showing the number of spots, their distribution in latitude, and the distribution of the faculæ in latitude.—L. **Décombe**: The direct calculation of the secular perihelic displacement of the planets on the hypothesis that the gravitation is of electrical origin. Application to the planet Mercury.—F. **Michaud**: The rigidity of jelly. The influence of a dissolved crystalloid. An application of a method described in an earlier note, capable of measuring a modulus of rigidity one-hundredth of that measured by Schwedoff. The effects of adding acids, bases, mineral salts, and organic substances have been studied.—A. **Dauvillier** and Louis **de Broglie**: Remarks on the work of M. E. Hjalmar concerning the M series of the elements. The measurements recently published by Hjalmar confirm the theory of the structure of the Röntgen spectra of the elements developed by the authors.—G. **Durante**: An apparatus for microphotography. Simplicity, transportability, and low cost are the advantages claimed for the apparatus described.—Georges **Déjardin**: The ionisation of mercury vapour in the presence of argon. The phenomena described in detail can be best explained by assuming that for electrons traversing an atmosphere of argon there exists a first critical velocity corresponding to about 11·3 volts, and that the resonance radiation emitted by the gas under these conditions ionises the vapour of mercury. This ionisation is not accompanied by any notable modification of the mercury spectrum.—G. **Denigès**: The rapid estimation of magnesium in a single drop of sea-water. The method is based on Schlagdenhaufen's reaction, the colour produced by the interaction of magnesium salts and potassium hypoiodite.—L. J. **Simon** and A. J. A. **Guillaumin**: Methylisopyromucic acid and a method of diagnosis of the acids of the sugar group. The dehydration of the lactone of rhamnonic acid gave methylisopyromucic acid, a description of which is given.—Marcel **Delépine**: The dipyridine iridium tetrachlorides. Configurations of the iridio-dipyridinotetrachlorides.—M. **Picon**: The action of sodammonium on aniline and its homologues. Sodammonium (in liquid ammonia) and aniline react slowly at the ordinary temperature giving hydrogen, sodium amide, and the aniline derivative $C_6H_5.NHNa$. The last named reacts violently with ethyl bromide, giving ethylaniline. Other aryl amines behave similarly.—E. E. **Blaise**: Syntheses by means of mixed organozinc derivatives: propylglyoxal.—Léon **Moret**: The existence of the upper Cretaceous (facies "Red layers") in the Autochthone in the neighbourhood of Thônes (Haute-Savoie).—F. **Roman** and J. Royo **Gomez**: The existence of Lutecian mammals in the Douro basin (Spain).—V. **Van Straelen**: The decapod crustaceans of the Portland beds of Cerin-Marchampt.—Henri **Coupin**: The origin of the siliceous carapace of diatoms.—A. **de Puymaly**: The adaptation to aerial life of *Zygnema peliosporum*.—E. **Chauvin**: The toxicity of *Volvaria gloiocephala*. This fungus, commonly considered as poisonous, when gathered near Algiers was shown by A. Gautier to be edible without inconvenience. The author has gathered the same fungus in France (Fontainebleau) and eaten it without ill-effects.—V. **Vincent**: The measurement of the acidity of soils by alkaline liquids.—L. **Fage** and R. **Legendre**: Fishing with a submerged source of light as a means of studying the coast fauna.—Mme. Z. **Gruzewska** and M. **Fauré-Frémiet**: The maximum quantities of reserve glycogen in the livers of dogs of different ages.—L. **Garrelon**, D. **Santenoise**, and R. **Thuillant**: The parallelism between the sensibility to the oculocardiac reflex and the sensibility to toxic actions.—Mlle. France **Gueylard** and M. Marcel **Duval**: The comparative toxicity of various acids for fishes (*Gasterosteus aculeatus*). The hydrogen ion concentration is not the sole cause of the rapid death

of the fishes in acidified solutions: the nature of the acid has also an important influence.—Aug. Michel: Caudal regeneration in *Polygordius neapolitanus*.—H. Barthélémy: The maturation *in vitro* and the activation by puncture of the ova of *Rana fusca* at the moment of discharge from the frog.—M. Charcot: Preliminary report on the voyages of the *Pourquoi-Pas?* in 1922.—A. Desgrez and H. Bierry: A mode of action of Vichy waters.

WASHINGTON.

National Academy of Sciences (Proc. Vol. 8, No. 11, November 1922).—J. A. Marshall: Bactericidal properties of the products of radium emanation. Old radium emanation tubes which have undergone disintegration in respect of γ-ray content are crushed under Ringer's solution in a sterile mortar. The radioactive solution obtained is conveyed immediately to the infected areas by sterile dressings; in the case of abscesses at the roots of teeth, it is injected through the pulp canal. This treatment gives better results than other antiseptic agents.—H. S. Washington: The jades of Middle America. The jades investigated are from a sacred natural well in the ancient Maya city of Chichen Itza, in northern Yucatan. The dominant colours are grey and green. They are jadeite jades of American origin, and differ from Asiatic jadeite in the large amount of diopside in the pyroxene they contain and the presence of much albite. Analyses are given.—Carl Barus: On a comparison of the relative sensitiveness of telephones. An interferometer U-gauge is connected by a quill tube to the telephone mouthpiece and a relation is obtained between the fringe movements and the constants of the instrument.—Carl Barus: The equilibrium positions of the vacuum gravitation needle in 1921 and 1922. From the curves given, the variations of the position of equilibrium in the lapse of time are of a different order in 1922 from their approximate constancy, in the given scale, in 1921. This may be due to the difference in the vacua obtained. All observations have a period of 24 hours, indicating solar radiation as the origin of the variations.—W. W. Coblenz: Further measurements of stellar temperatures and planetary radiation. (See NATURE, December 30, p. 886.) H. A. Lorentz: Proof of a theorem due to Heaviside. The theorem in question is: "The whole work done by impressed forces suddenly started exceeds the amount representing the waste by Joule-heating at the final rate (when there is any), supposed to start at once, by twice the excess of the electric over the magnetic energy of the steady field set up."—A. J. Lotka: The stability of the normal age distribution. There is an age distribution which, in certain circumstances, perpetuates itself when once set up in a population. An analytical method is used to show that this distribution is stable and that a population spontaneously reverts to it if the age distribution be displaced.

Diary of Societies.

SATURDAY, JANUARY 6.

ASSOCIATION OF WOMEN SCIENCE TEACHERS (at University College), at 2.30.—Dr. Dorothy Wrinch: Relativity.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. H. H. Turner: Six Steps up the Ladder to the Stars (5). Two Great Streams of Stars (Juvenile Lectures).

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W.C.1), at 3.—G. J. B. Fox: A Visit to Pompeii.

MONDAY, JANUARY 8.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—E. W. Moss, and others: Discussion on the Protection of Inventions by Letters Patent.

ARISTOTELIAN SOCIETY (at University of London Club, 21 Gower Street), at 8.—Rev. Leslie J. Walker: A New Theory of Matter.

SURVEYORS' INSTITUTION, at 8.—F. W. Hunt: Zoning in the Control of Large Cities.

TUESDAY, JANUARY 9.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. H. H. Turner: Six Steps up the Ladder to the Stars (6). The Size of a Star. (Juvenile Lectures.)

SOCIETY FOR THE STUDY OF INEBRIETY (at Medical Society of London), at 4.—Dr. H. Campbell and others: Discussion on The Pathology and Treatment of Morphia Addiction.

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30.—Dr. W. R. Ormandy and E. C. Craven: Further Investigations into the Physico-Chemical Significance of Flash-Point Temperatures.

MINERALOGICAL SOCIETY (at Geological Society), at 5.30.—A. Brammall and H. F. Harwood: Dartmoor Granite: (*a*) Rutile, Brookite, and Anatase: Genesis. (*b*) Varieties of Zircon: their significance.—Dr. A. Hutchinson: A Graphical Method of Correcting Specific Gravity Determinations.—Dr. L. J. Spencer, with microscopical determinations by W. Campbell Smith, and chemical analyses by E. D. Mountain: A Davyne-like Mineral and its Pseudomorphs from St. John's Island, Egypt.

INSTITUTION OF CIVIL ENGINEERS, at 6.—H. W. H. Richards: Twelve Years' Operation of Electric Traction on the London, Brighton, and South Coast Railway.

INSTITUTE OF MARINE ENGINEERS, INC., at 6.30.—H. Campbell: Gas Engines, and Gas Producer Plants.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Scientific and Technical Group), at 7.—H. W. Greenwood: The Manufacture of Paper for Photographic Purposes. Historical—Hand-made Paper—Machine-made Paper—Raw Materials—Preparation—Beating—Sizing—Making—Finishing and Baryta Coating. Faults of Manufacture and their Effect on Emulsions—Testing for Faults, Impurities, etc.

QUEKETT MICROSCOPICAL CLUB, at 7.30.—Various Members: Notes on Mounting.

CIRCLE OF SCIENTIFIC, TECHNICAL, AND TRADE JOURNALISTS (at Institute of Journalists), at 8.15.—Sir Richard Gregory and others: Discussion on Reviews and Reviewers.

WEDNESDAY, JANUARY 10.

ROYAL SOCIETY OF ARTS, at 3.—C. R. Darling: The Spectrum, its Colours, Lines, and Invisible Parts, and some of its Industrial Applications (Dr. Mann Juvenile Lectures (2)).

GEOLOGICAL SOCIETY OF LONDON, at 5.30.

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—C. F. Elwell: Design of Radio Towers and Masts: Wind Pressure Assumptions.

INSTITUTION OF AUTOMOBILE ENGINEERS, at 7.30.—Col. P. H. Johnson: Improvements in Efficiency of Roadless Vehicles.

THURSDAY, JANUARY 11.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 3.—R. A. Frazer: Testing Model Seaplanes (Juvenile Lecture).

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7.30.—C. Davidson: The Amount of Displacement in Gelatine Films shown by Precise Measurements of Stellar Photographs.—J. E. Barnard: The Use of Ultra-violet Light in Microscopy.—F. W. Preston: Pitch.—T. Y. Baker: A Prismatic Astrolabe.

INSTITUTE OF METALS (London Section), (at Institute of Engineers, Inc.), at 8.—W. E. Hughes: Some Aspects of Electro-deposition.

CAMERA CLUB, at 8.15.—J. S. Wells: Criticism of Members' Prints.

FRIDAY, JANUARY 12.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Prof. A. S. Eddington and A. V. Douglas: The Progression of Stellar Velocity with Absolute Magnitude.—J. Evershed: Note on the Corona of 1908.

MALACOLOGICAL SOCIETY (at Linnean Society), at 6.

INSTITUTION OF HEATING AND VENTILATING ENGINEERS, INC. (at Engineers' Club, Coventry Street), at 7.—Dr. B. R. Wingfield: Automatic Temperature Control.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—S. A. Stigant: Transient Phenomena arising in Transformers from Switching Operations.

ROYAL SOCIETY OF MEDICINE (Ophthalmology Section), at 8.30.—H. Butler: Some Unusual Cataract Operations.—C. Killick: The Treatment of Conical Cornea.

SATURDAY, JANUARY 13.

GILBERT WHITE FELLOWSHIP, at 2.15.—Visit to the Geological Museum, Jermyn Street.

LONDON.

NATIONAL UNION OF SCIENTIFIC WORKERS.

25 VICTORIA STREET, LONDON, S.W.1.

The ANNUAL COUNCIL MEETING of the UNION will be held at the Caxton Hall, Westminster, on Saturday, January 13, 1923, at 2.30 P.M.

The ANNUAL DINNER of MEMBERS of the UNION will be held at the Florence Restaurant, Rupert Street, W.1, on Saturday, January 13, 1923. Assembly, 7 P.M. Morning Dress.

The GENERAL SECRETARY, N.U.S.W., will be obliged if members wishing to attend would make immediate application to him.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY,

SOUTH KENSINGTON, S.W.7.

DEPARTMENT OF OPTICAL ENGINEERING AND APPLIED OPTICS.

The usual Classes are being continued during the SPRING TERM, and in addition the following will be given:—

COLOUR AND ITS MEASUREMENT.—A Course of TEN Weekly Experimental Lectures beginning on Tuesday, January 16, at 6.30 P.M. will be given by Dr. L. C. MARTIN.

THE MECHANICAL DESIGN OF THE COMMON MICROSCOPE.—A Course of SIX Weekly Lectures will be given by Professor POLLARD on Thursday at 6 P.M., commencing January 18.

For further particulars and for admission tickets apply to the REGISTRAR at the above address.

The Director is open to receive applications from students and others desirous of carrying out research work in the Laboratories.

UNIVERSITY OF LONDON.

A Course of eight Lectures in Physiology on "THE MATHEMATICAL BASIS OF PHYSIOLOGICAL PROBLEMS" will be given by MR. W. A. M. SMART, M.B., B.S., M.R.C.S., L.R.C.P., B.Sc., at the LONDON HOSPITAL MEDICAL COLLEGE (Turner Street, Mile End, E.1) on THURSDAYS, January 18 and 25, February 1, 8, 15, 22, and March 1 and 8, 1923, at 4.30 P.M. ADMISSION FREE, WITHOUT TICKET.

EDWIN DELLER, Academic Registrar.

UNIVERSITY OF CAPE TOWN.

SENIOR LECTURESHIP IN PHYSIOLOGY.

The University invites applications for the POST of SENIOR LECTURER in the DEPARTMENT of PHYSIOLOGY at a salary of £450 per annum rising by annual increments of £25 to a maximum of £650 per annum. (The successful applicant, if a qualified medical practitioner, will be allowed a salary of £500 for the first three years of his appointment.)

An allowance of £40 will be made for passage money.

The lecturer must become a member of the University Teachers' Superannuation Fund.

The successful applicant will be expected to assume duty on March 12, 1923, or as soon thereafter as possible. Salary commences from date of assumption of duty.

Applications and copies of testimonials, all in duplicate, must reach the SECRETARY, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C. (from whom Forms of Application and further particulars may be obtained), not later than January 31, 1923.

UNIVERSITY OF LONDON.

The Senate invite applications for the UNIVERSITY CHAIR of ZOOLOGY tenable at Bedford College. Salary £800 a year. Applications (12 copies) must be received not later than first post on April 16, 1923, by the ACADEMIC REGISTRAR, University of London, South Kensington, London, S.W.7, from whom further particulars may be obtained.

INSTRUCTOR—Physics or Mathematics.—For one or more terms, London area. M.A., first-class honours, 1910 (also full B.Sc. courses). 3 years' experience lectures and demonstrating, also in Economics. Box 46, c/o NATURE Office.

GERMAN GENTLEMAN (30) requires position of trust with optical instrument firm in England. Ten years' experience with renowned scientific instrument firms in Germany. Holder of States-certificate for opticians. Reply, Box 1346, NATURE Office.

NO. 2776, VOL. 111]

The British Empire Exhibition, 1924.

THERE is to be held, from April to October 1924, in Wembley Park, six miles by road from the Marble Arch, London, on ground occupying about 150 acres, a great exhibition displaying the immense resources, both industrial and productive, of the British Commonwealth, which now extends over one-quarter of the known surface of the globe and has a population exceeding one-quarter of its inhabitants. Its main purpose is to promote the exchange of raw material and manufactured goods within the Empire, an entirely worthy object. As the prospectus says, "We possess every kind of climate, every kind of mineral wealth, every potentiality that is known to the world. We have the best race of men to use and develop them." Under the present seriously disturbed commercial conditions, the value of the general trade of the United Kingdom in 1921 was, of imports, 1,085,500,061*l.*, of which the British Dominions supplied 303,859,326*l.* and foreign nations 781,640,735*l.*, and of exports 810,318,848*l.*, of which the British Dominions took 292,393,701*l.* and foreign nations 517,925,147*l.*

In 1913 we imported from Germany 1,731,000*l.* worth of synthetic dye-stuffs and 146,000*l.* worth from Switzerland, and it is estimated that we bought from British producers about 100,000*l.* in value. Yet the coal-tar colour industry began here both scientifically and commercially from the incidental discovery by Perkin, while engaged in another organic investigation, of a mauve colouring matter derived from coal-tar. It was in 1854, when Perkin was sixteen years of age and a student at the Royal College of Chemistry, Queen Street, London, under A. W. Hofmann, formerly of Bonn University, who was appointed at the instance of Prince Albert (the chief promoter of the Great Exhibition of 1851) director of the Royal College in 1845. From 1856 to 1865 Hofmann was chemist to the Royal Mint. He afterwards went to Berlin as professor of chemistry, where his work covered a wide range of organic chemistry. Perkin's discovery, having regard to our vast supply of raw material, led to the confident anticipation that Great Britain would in future be the dye-producing country of the world. But this was not to be. Its development, mainly because of the lack of facilities here for the supply of adequately trained scientific men, and because of the advanced condition of German scientific education which had been sedulously fostered, took place in Germany, and for the future years our textile and other industries, to the extent of their output of dyed goods (which now exceeds in annual value 200,000,000*l.*), were

dependent for the supply of synthetic dye-stuffs upon Germany and Switzerland.

The importance, however, of a large supply of scientifically trained men, especially in chemistry, and the production of synthetic colouring matters on a large scale, sufficient to entitle it to rank as a chief key industry, have not merely an industrial significance; they have military aspects as well, since the discoveries and the applications of science may be used for evil purposes as well as for good, as the history of all wars shows. During the great war the Germans resorted to the use of poison gas, and thus started a course of "chemical warfare." The production of poison gas in its many forms was made possible because Germany had a fully developed dye-stuff industry, not merely in its personnel, but also in the perfection and extent of its plant, and the organic substances which were used and the methods employed were closely related to those required in the manufacture of synthetic colours. The Allies entered upon similar methods of attack, but in order to provide the means, except in the case of one large manufacturing firm producing dye-stuffs in Manchester, they had to erect special factories for the purpose.

If, however, we succeed in establishing coal-tar dye industries on a scale sufficient to meet the demands of our manufacturers, alike in quality, quantity, and price to those of our foreign competitors, we shall no longer have any cause for fear either in respect of our industries or in the event of war. But in order to achieve this and other desirable aims, we have to emulate the spirit and adopt the means and methods of the most progressive nations for the encouragement of scientific research and its application, together with the opportunity of advanced education for all who are worthy to receive it. The experience to be gained from previous exhibitions on a similar scale held at home and abroad, and the results accruing therefrom, should not be overlooked. The British Empire Exhibition to be held at Wembley, if it is not to miss a serious and fundamental purpose, must awaken a spirit of emulation for a wider extension of the means of knowledge and better conditions whereby its fruits can be achieved.

The Great Exhibition of the Industries of All Nations, of 1851, was remarkable from the fact that the building covering twenty acres of ground was erected of glass and iron after the designs of Joseph Paxton—a fine example in itself of the genius of the English engineer and a triumph of his technical skill. The exhibits were arranged under four heads: 1. Natural productions; 2. Machinery; 3. Manufactures; 4. Works of Art. It was attended by upwards of six million people of all nations. It was a financial success, the profits of which were invested in land at South Kensington on which numerous institutions for the advancement of science and art have been placed. "There began with it," says J. Scott Russell in his book on "Systematic Technical Education," "a series of competitive trials of intelligence and skill between the citizens of the different civilised nations of the world." We were supreme in the sphere of modern manufacturing machinery, but in respect of matters of taste and artistic design and skill we were far behind the French. The direct fruit of it all was, so far as this country was concerned, to be found in the organisation of the Science and Art Department (1853), whereby was brought within the reach of the workman, whether engaged in a mechanical or artistic handicraft, the means of study and experiment in the principles of his occupation. It reacted similarly on the educational policy of foreign nations, especially in France and Germany. They established schools of applied science according to the special needs of the town or industrial centre, the results of which were seen in the exhibition held at Paris in 1855, and especially in the International Exhibition held at South Kensington in 1862. There was abundant evidence that while we had progressed greatly in artistic taste and skill in design and workmanship, other nations had advanced in the industrial applications of science. There was Prussia with her ingots of Krupp steel, Switzerland with her fine display of Schönbein aniline colours, America with her automatic machines, Italy with her manufactures of classic earthenware, France with her fine steam-engines for her marine service.

"It was [however] the exhibition of 1867 in Paris," says J. Scott Russell (he was one of the English jurors), "which gave the nations, and especially England, a final lesson. By that exhibition we were rudely awakened and thoroughly alarmed. We then learnt, not that we were equalled, but that we were beaten—not on some points, but by some nation or other on nearly all those points on which we had prided ourselves."

There was shown the engineering products of a great establishment at Creusot in Eastern France concerned with mining, smelting, locomotive building, and other branches of commercial machinery in serious competition both in quality and price with like products from England. In addition to abundant raw material on the spot, coal and iron ore, the workers had the advantage of a systematic o ganisation of technical schools, which contributed very largely to the satisfactory results produced.

The Centennial Exhibition, held in Paris in 1900, furnishes another example of the value of these inter-

national exhibitions to the progress of industrial science. It was a marvellous display of executive skill and arrangement, and is well worthy of the closest study. Whether regarded from a constructive and engineering point of view, or from that of form and colour, the various features of the exhibition were endless in their variety and offered the most suggestive examples to the engineer, the designer, and the artist. A striking feature of the exhibition was the extent of space given to the display of facilities of education in France from the primary schools to the most advanced means of scientific and technical training. This was not confined solely to France, but other countries joined in it, notably the United States of America, which made a fine display. The exhibit arranged by South Kensington of gold-medal and other premiated works in the annual National Art Competitions challenged the admiration of foreign critics and caused the French authorities to say that they wondered, since such excellent designs could be produced, how it was that English manufacturers came so largely to France for designs. Another notable feature of the exhibition was the joint display of German scientific instruments. The exhibit was arranged collectively by ninety-eight German firms of instrument-makers, and was placed in charge of a scientific expert with qualified assistants, who undertook to explain and demonstrate to inquirers the purpose and merit of the various exhibits. Such an example of co-operation may be commended to the notice of the executive committee of the British Empire Exhibition.

The desirability of a special display of the educational activities of the various dominions of the Empire may also be suggested, such, for example, as was arranged with marked success for the United Kingdom at the Franco-British Exhibition held in London in 1910 in a specially adapted building, which included a lecture hall.

Having regard to the numerous research boards and committees for the investigation of scientific industrial problems under the auspices of the Department of Scientific and Industrial Research, the seventh annual report of which has lately been issued, and also to the existence of many separate societies for a like purpose, it seems appropriate that a special building or Hall of Science should be provided, in which lectures, experiments, and demonstrations illustrating many aspects of scientific work and discovery should be constantly arranged, as was done at the successful Scientific Novelties Exhibition just concluded at King's College, London. Such provision would give a living interest to the exhibits and serve to stress the the importance of purely scientific research in the development of industry.

Area of Distribution as a Measure of Evolutionary Age.

Age and Area: A Study in Geographical Distribution and Origin of Species. By Dr. J. C. Willis. With chapters by Hugo de Vries, H. B. Guppy, Mrs. E. M. Reid, and Dr. James Small. Pp. x+259. (Cambridge University Press, 1922.) 14*s.* net.

TO determine the value of Dr. Willis's book is not easy. The author delivers his message with enthusiasm and emphasis. "Age and Area," he reiterates, provides a penetrating and wholly new light on evolution. His supporters, four of whom contribute chapters to the book, endorse this opinion and tell us it is all right. Table after table exhibits special phenomena on which Dr. Willis relies. These tabulations seem to have been scrupulously made, and they certainly demonstrate some remarkable and novel results. The book is written with perfect sincerity and a conviction almost naive. Whatever its worth may prove to be, it is an honest attempt. So imposing an array must produce an effect in the mind even of the critical. But there are disquieting features. Repetition of the bald assurance that Age and Area is the true faith should be unnecessary. A judicious advocate would leave that conclusion to flow more quietly from the evidence. When, for example, we read, "As one of our leading ecologists says in a letter to me, and underlines, 'this will be strongly in favour of your Age and Area hypothesis,'" we remember seeing testimonials like that elsewhere and in more mundane application. But though the reader's scepticism is thus instantly aroused, the matter is worth careful attention, for to have hit on a new method of investigating even a part of the theory of evolution is no common achievement, and that the author has done this cannot in fairness be denied.

The main idea is not difficult to grasp. It is simply that, subject to various provisos, the area which a species "occupies" upon the earth is a measure of its antiquity in evolution. "Occupy" is scarcely a fortunate word in so formal a definition. The area "occupied" by a species has immediately to be explained as meaning the area over which the species *extends*, or has extended as shown by the fossils. Lingula lives now in the Chesapeake and in Philippine waters, but to speak of it as "occupying" the whole world would be confusing, even though it is found fossil in many countries.

A species once evolved is conceived as spreading in an ever-widening circle, much as a culture may do, inoculated upon a gelatine plate. If the medium be homogeneous and growth be undisturbed, the size of

the circle will be a function of the age of the culture until the medium is covered. The species or genera in the course of their dispersal are held to throw off new species and new genera, each of which again spreads concentrically from the focus of its inception. The throwing off of these new forms of life is regarded by Dr. Willis as a "casual" process, and regarding it some very definite inferences are drawn, of which we will speak later.

Now every evolutionist agrees that, *apart from disturbing elements*, area is a measure of age. If the matter rested there nothing would be in dispute, but nothing fresh would have been contributed to the discussion. We are, however, asked to believe that in practice this mode of estimating the age of a species is, on the whole, trustworthy: that endemic species and rarities in general can and must be for the most part accepted as new starters in evolution, and not as survivors. That is, of course, a paradox, but it constitutes the main thesis of the work. Dr. Willis takes the floras of Ceylon and New Zealand into special consideration, besides those of other isolated places, mountain tops and remote islands, and in brave defiance of all that science has hitherto taught us regarding the peculiar plants and animals limited to such localities, he tells us that, on the whole, the reason why those creatures occupy such small areas is that they have not yet existed long enough to have spread far. If any one objects that in application to the special cases which immediately suggest themselves, Sphenodon, the dodo, Leucodendron, etc., such a contention is preposterous, Dr. Willis would reply that he knew as much already, and that he is concerned not with special cases, but with averages and general propositions. He is within his right. The second proviso is that comparative estimates of age are only to be based on area when forms within the same "circle of affinity" are compared.

Everything then turns on the computation of these averages and on the criteria by which "circles of affinity" are to be recognised. Unfortunately no means are suggested by which we are to tell whether a species or genus is a novelty or a relic, and obviously none can be forthcoming. We may make shrewd surmises, but if things like that could be declared with certainty the study of evolution would be on the way to becoming an exact science. Meanwhile estimates of age based on area "occupied" must be exceedingly hazy. Giant tortoises live in the Mascarenes and in the Galapagos, and therefore must be reckoned ancient, as they doubtless are. When they become extinct, say in the Mascarenes, which they presumably will, they would start again as novelties at the bottom of the list, but for the accident that the remains of such creatures form conspicuous fossils. Of the New Zealand shrubby Veronicas one, *V. elliptica*, occurs also in Fuegia; having the widest recorded range it must be deemed by far the oldest of these species. Once extinct in either locality, whether Fuegia or New Zealand, it would be ranked with the rest of the New Zealand species as new mutations.

Then again the surface of the terrestrial globe is, as we all know, a medium of complex heterogeneity. By no provisos, safeguarding clauses, or anticipatory exclusion can considerable areas be defined in which dispersal may be observed which has not been promoted or limited, diverted or arrested, by countless interferences. Very rarely, if ever, do we find that reasonable uniformity and constancy of conditions, even in space, let alone time, without which we are warned the theory must not be applied. In areas which may be judged most uniform at a given point of time, the operation of sharply limiting causes is manifest. If, as in prairies and steppes, for hundreds of miles the conditions appear geologically and meteorologically uniform, the mere presence of living things introduces heterogeneity. Dr. Willis is well aware of this. In one of his best chapters he discusses "barriers" in the widest sense, and he makes us realise how difficult it must be for a new-comer species to get a footing or to spread among plant-associations already established. On the Central Asian steppes, for example, one can distinguish on the remote horizon by their colour the spots where encampments have stood. These patches are mainly characterised by the presence of nettles, which grow in such places. Nettles, as Dr. Willis remarks, are very easily dispersed by wind, yet nowhere else do they establish themselves in the Artemisia steppes—only in places which man and his animals have made fit for their growth. European weeds abound in the Eastern States where the soil has been cultivated, but few invade patches of unbroken territory. Quantitative estimates of the allowances to be made for heterogeneities and barriers in general cannot be attempted. Therefore in the hope that the heterogeneities will be so many and so various as to cancel, a reservation is introduced to the effect that the groups of species to be compared should each be not less than ten in number. But the difficulty is a real one, and in dealing with any troublesome or unconformable phenomena these considerations provide endless loopholes for escape.

A still more formidable difficulty is encountered in the endeavour to declare which classes of forms may be compared legitimately with the object of determining their relative ages from the areas they occupy, and which are not comparable. To have some con-

existent criterion by which comparables may be recognised is absolutely essential to the application of the method. Nevertheless no information offered reduces the difficulty materially. We are told that only forms in the same "circle of affinity" are to be taken—a definition which is plainly left vague deliberately. How this is to be construed we are never precisely told. The species to be compared must be more or less alike in their modes or at least in their facilities of dispersal—a property we have commonly no means of estimating in any trustworthy or quantitative way. Unless I have misunderstood the chain of reasoning, its validity is severely strained at this point.

The author is shy of special illustrative examples and they need not be essential to an argument dealing solely with general propositions, but in a chapter contributed by Prof. Small we are provided with an illustration on the largest scale. There we are given to understand that the natural order Compositæ is a "circle of affinity" to which the method of Age and Area can be properly applied. If a group so polymorphic and heterogeneous as the Compositæ constitute a "circle of affinity," the members of which can be compared for these purposes, where are we to stop? The tribes of Compositæ are arranged in a genealogical tree upon which the presumed point of origin of each is marked, and we are told that the order of evolution as given on the tree, which has been constructed from anatomical data, agrees substantially with the numerical estimate of the areas occupied by each tribe. Needless to say, numerous eminent botanists have arranged the tribes in almost as many other ways, probably with equal propriety. These speculative genealogical trees, once fashionable, are, I had supposed, discredited. All that they can attempt is the display of a logical order of interrelationship based on the modifications of the special set of organs selected as a criterion; for the Compositæ this order will differ with each set of organs chosen. In support of Prof. Small's arrangement he gives an imposing tabulation of the geological levels in which each tribe is believed to have arisen. Not until the text of Prof. Small's previous papers is consulted does a reader discover that this tabulation is almost wholly conjectural. In a well-written and judicious chapter by Mrs. Reid, who discusses what palæobotany can produce in support of Age and Area, we find no such confident pronouncements. The inclusion of the chapter on the Composites reflects more credit on Dr. Willis's candour than on his scientific judgment. The propositions made in the name of the theory there stand forth with a neglect of caution which Dr. Willis himself seldom exhibits.

For the reasons given, the theory of Age and Area, except in so far as it is truistical, is as yet of doubtful value, and unless amended to meet the difficulties specified it cannot be applied with any confidence. I suspect that certain predictions respecting the flora of the islands near New Zealand, which, though made in advance, as we are frequently reminded, were fulfilled, did not involve any feat of which common sense would have been incapable.

Dr. Willis is a great advocate of the theory of mutation in its crudest form. The speculation now presented to us as Age and Area is a development of an idea which came to him when he reflected on the fact that in Ceylon several endemic species are limited to small areas, though sometimes associated with related species of wider distribution. The theory of mutation of de Vries appeared at about the same time, and Dr. Willis asked himself whether the wonderful "mutations" which had been reported in Œnothera might not exemplify the process by which the Ceylonese endemics had been begotten by the "wides," as he calls them. Endemics had previously been held to be largely relics. In the new light they become "in the vast majority" novelties, about to spread with the lapse of time in widening circles. On any theory of evolution endemics must be in part novelties and in part relics; but why, apart from the theory of Age and Area, we should believe that endemics are in such great majority novelties I do not clearly understand, for though we know little of origins we are certain that myriads of species have become extinct. It is surely contrary to all expectation that the process of extinction should be in general so rapid, and the final endemic phase so short that the number of species in that final stage of existence should be insignificant.

The supposition implies the optimistic but embarrassing corollary that a species, once established, is in no great danger of extermination unless some catastrophic or lethal change occur in the conditions of life. *Cupressus macrocarpa* is admitted to be in danger because, as we are told, the Monterey peninsula is drying up. This is used as the stock illustration of the mode in which authentic extinction should occur. As it serves three times in this capacity, bearing perhaps an undue burden in the argument, we may infer that examples of extinction through predicable secular change are not plentiful. Unless, indeed, the change can be traced directly or indirectly to human action, the cause whether of gain or loss of territory is apt to be a mere matter of surmise, for though losses are so familiar we must not forget that there are also mysterious gains—even in our own area. Who shall say what gave *Capros aper* its chance? A doubtful British species in the time of Couch, it

became a nuisance in the trawl, some time at least in the eighteen-eighties. How did the showy *Plusia moneta* become a common British moth? No one recorded it here before 1890. Extinction must ensue from countless causes. If compelled to specify one class of cause as operating rather than another, we should regard the appearance of a new and antagonistic organism as by far the most formidable and effective agency of extinction; but we have only to glance at anthropological data to observe that no rule obtains as to the length of time which the process of extermination will take. Whatever doubts be entertained as to the significance of adaptation in delimiting *specific characters*, there can be none that survival is determined by selection according to the balance of the profit-and-loss account on the workings of the machine.

Wondering at the Ceylonese endemics, Dr. Willis asks rhetorically, "Had one arrived in Ceylon just in time to see the disappearance of a considerable flora?" We may reply, What more likely? Is the alternative interpretation, that he had come in time to attend the birth of a new flora, more acceptable? About half the endemics of Ceylon, he tells us, occur on the tops of single mountains or small groups of mountains. Does he really suppose that future ages will witness the spread of such species downwards from the mountain tops?

In reading the chapter on the origin of species and the many passages in which references to mutation are made, I see signs that Dr. Willis, though making large assumptions in the name of genetical experiment, is not sufficiently conversant with the present state of genetical science. Both from observation and from experiment, the certainty that variation is largely discontinuous has been established. If for the moment we abrogate the consideration of interspecific sterility we might declare that forms mistakably like new species do actually arise suddenly. But this is scarcely mutation as contemplated by the theory of Age and Area. If we were told categorically which "wide" species is regarded as the putative parent of which endemic, we should be in a position to consider how far this interpretation is consistent with what we know of variation. From anything so precise Dr. Willis shrinks. Here and there we get a glimpse of what he would like us to infer. The endemic *Coleus elongatus*, for example, he is inclined to claim as the immediate product of *C. barbatus*, from which it differs in some ten respects. The shrubby Veronicas are characteristic of New Zealand; if pressed Dr. Willis would point to the "wide" *V. elliptica* (mentioned above) as their putative parent. Similarly the Chilian *Ranunculus acaulis*, or alternatively *R. crassipes* (found in Kerguelen), which both occur in New Zealand, might be adduced as the parent of the endemic Ranunculi of those islands. Though undeniable as possibilities, we have to consider what warrant for such guesses can be drawn from the observed facts of variation. The answer is quite clear that up to the present scarcely anything comparable has been observed. The "rogue"-peas, the "fatuoid" mutations of oats (Nilsson-Ehle and later Marquand), with perhaps a very few more, are all that can be quoted as precedents, none certainly in point. No one familiar with genetical work would be disinclined to entertain the supposition that such groups of endemics as the New Zealand Veronicas may not improbably be co-derivatives from one or more crosses; so also may the hosts of "species" of Cratægus which Prof. Sargent has described largely as endemics on derelict farms of the Eastern States. But to establish these propositions, genetical and doubtless cytological work on a vast scale is required, and far too little has been yet done to justify the bold assumptions lightly made in the doctrine of Age and Area.

The evidence adduced by de Vries from Œnothera which led him to propound the theory of Mutation is clearly enough the precedent which Dr. Willis has at the back of his mind. From the first the meaning of the Œnothera work was ambiguous. The researches of Renner and of Heribert-Nilsson have now shown that those early suspicions were justified, and that the "mutations" of Œnothera are not genuine illustrations of the origin of species by variation in descent from a pure form. Had de Vries grasped the implications of Mendelian analysis, he could never have so interpreted them with any confidence. The few words in which he conveys his benediction on this new venture should be read with caution and reserve by persons unfamiliar with the history they purport to relate.

Unconvincing as the main argument of "Age and Area" appears, the reader will find in it some curious and interesting discoveries. Of these the most remarkable is the uniformity of the statistical distribution of species among the genera of various and most dissimilar forms of life, both plants and animals. The monotypic genera, with one species each, are always the most numerous, commonly forming about a third of the whole group, the ditypics, with two species each, are the next in frequency, genera with higher numbers of species becoming successively fewer. Set out graphically, according to the number of species they contain, the genera exhibit what is here called a "hollow curve" of frequency, and there is no gainsaying the fact that these curves, though collected from such miscellaneous sources, have a remarkable similarity. Another curious feature exhibited by this

marshalling of the genera according to the number of their species is not merely that the percentage of monotypes is largest on islands (as might be expected), but that it is exceptionally high in S. America and in Africa. The corresponding curves from several other regions are altogether different. I do not wholly follow the argument by which these features of regularity are interpreted as giving strong support for the theory of Age and Area. Whatever be the meaning of the regularity of the curve of frequency of species distributed according to genera, the occurrence of order in this unexpected place does not readily accord with the Darwinian view that specific diversity is primarily or closely dependent on fitness. That deduction, which looked so attractive in the superficial survey which was all that could be undertaken in Darwin's time, became practically untenable so soon as the phenomena of variation were accurately explored, and it is not surprising that close investigation of another part of the species-problem has revealed a similar weakness.

On the other hand, though the point is a minor one, the considerations collected under the title "Size and Space," though adduced as fatal to the theory of Natural Selection seem to have little cogency. On the average, genera with more species are shown to extend over greater space, and hence the area occupied by a genus corresponds roughly with the number of species it contains. What else could we expect? A large college, with a larger and more varied supply of competitors, commonly shows more successes (and indeed more failures) in more varied departments of activity than will be achieved by a smaller establishment.

One excellent purpose Dr. Willis's book will certainly serve. It will renew the debate on the mode of evolution, which for many reasons has of late years languished. Whatever doubts arise regarding the new deductions, Dr. Willis once more makes geographical distribution a live study, showing quite unexpected lines along which it may be pursued. The delimitation of floral areas—or, for that matter, zoological areas too—was, as he says, a dull and almost futile exercise of scholasticism. The introduction of statistical methods, here altogether appropriate, offers great possibilities.

In stronger hands a still greater effect might have been produced. The style of presentation scarcely attains the level required of such works by an age not over-exacting in that respect. Finish is no longer demanded of scientific authors, and we have come to suppose that loose writing is compatible with clear thinking. None the less it makes very difficult reading. Those who are not alienated by such blemishes will find the book interesting as a challenge. How far the new ideas are of value and how many of them are fallacious we shall scarcely know till they have been tried in practice over wide fields of experience, and examined in perspective from many aspects.

W. BATESON.

The Internal Combustion Engine.

The Internal-Combustion Engine. By Harry R. Ricardo. Vol. 1: *Slow-speed Engines.* Pp. vii+488. (London and Glasgow: Blackie and Son, Ltd., 1922.) 30*s.* net.

MR. RICARDO has completed the first volume of his promised book on the internal combustion engine, and according to the preface "hopes shortly to be able to complete the second." Seeing that the present volume deals entirely with the slow-speed engine, and was for the most part written many years ago, it is to the volume to come, dealing with the modern high-speed engine and embodying the results of recent researches, that the readers of NATURE will turn with greater interest. Mr. Ricardo is giving us two books rather than two volumes of one book, and it is a pity therefore that the volume now completed is not provided with an index.

The development of the internal combustion engine coming so much later than the steam engine, it was natural that during infancy its progenitors should be more disposed to seek the aid of physics and chemistry as god-parents than had been those of its rival, the steam engine, which received this baptism only in riper years. It is refreshing to a student of science to see how—and in Mr. Ricardo's contributions in particular—the limits of internal combustion engine design are studied in the light of modern knowledge of the detonation of compressed gases, flame temperature and flame velocity, the effect of change of specific heat, the effect of mass on dissociation. The results are very striking. The investigator of a new problem, instead of groping for a solution in the dense thicket of possibilities, is able, by using the laws of physics and chemistry as guides, to mark off the possible from the impossible, and so to reduce the area to be cleared to very much smaller dimensions. One catches the process at work in the volume before us, but for the culmination of its productiveness one has to wait for the stimulus of the war period with its impetuous demand for new engines for more and more effective flight. The impetuosity of this demand is illustrated by M. Rateau's recent paper at the Institution of Mechanical Engineers: two long-unsolved problems of the internal combustion engine are the compounded engine and the gas turbine: the needs of aviation are shown by M. Rateau insistently to demand some sort of solution of both these problems

at once, to enable flight at really high altitudes to be possible.

In the present volume Mr. Ricardo covers a wide field: all important types of slow-speed engine are described. Some of the work is thus rather that of editor than author, but opportunity for the exercise, at its best, of the latter rôle is seen particularly in the sections relating to engine balancing and piston friction, where the subject is dealt with in masterly fashion and cleared of the unnecessary complication so often found in other books on this subject. Some writers have photographic vision, Mr. Ricardo's is selective and acute. We receive this volume of his book with interest, and look for the second with pleasure. H. E. W.

Lord Moulton.

The Life of Lord Moulton. By H. Fletcher Moulton. Pp. 287+8 plates. (London: Nisbet and Co., Ltd., 1922.) 15*s.* net.

MR. FLETCHER MOULTON'S life of his father is an attractive volume which gives a vivid picture of the career of a man of remarkable ability. Beginning with very scanty financial resources, Lord Moulton spent some three and a half years as an assistant master after leaving school before he entered for a scholarship at Cambridge. During this time, however, he carried off three successive scholarships at the University of London, and so established a record of success which remained unbroken during his time at Cambridge.

Two consecutive chapters describe Lord Moulton's work at the Bar and on the Bench, first of the Court of Appeal and then as a Lord of Appeal and a member of the Judicial Committee of the Privy Council. The latter part of the book is given up to a description of his work during the war, and to those successful efforts which made it possible to assert that in this country, at any rate, empty shells were never kept waiting for supplies of explosives with which to fill them. For a solution of this most difficult problem of supply Lord Moulton relied mainly on the production and utilisation of a very large output of ammonium nitrate, and the principal chapter devoted to this period of Lord Moulton's life bears the appropriate title of "The Fight for Amatol." In this fight he was handicapped, not only by the inertness of this explosive, which in the early days created a well-deserved prejudice against it, but also by the difficulty of turning down inferior and sometimes fraudulent substitutes when these were advocated with the aid of influential supporters.

The most notable of these substitutes was "Halakite," a new and wonderful explosive, alleged to be capable of acting both as a propellant and as a high explosive, with the additional advantage of containing no nitroglycerine. The first samples supplied by the inventor were found, however, to contain 20 per cent. of nitroglycerine, and samples supplied to the French Government consisted of British Mark I cordite coloured yellow with lead chromate. The twenty pages devoted to this case are probably a fair measure of the amount of time that was absolutely wasted by Lord Moulton's department when the inventor had found an editor sufficiently influential to work up a scandal but also sufficiently ignorant to be taken in by his claims. Lord Moulton himself had, however, a remarkable ability for detecting real promise in the propositions put before him, and in nearly every case where a difference of opinion arose, subsequent experience showed that Lord Moulton was right and his critics were wrong. This was notably the case in reference to amatol, which remained not merely in service throughout the war, but is generally recognised as providing one of the best fillings now available for H.E. shells for land service.

A chapter is devoted to Lord Moulton's scientific work; but although a summary is given of his experiments with Spottiswoode, the usual references by which a scientific reader would trace this work are not given. An examination of the Royal Society's Catalogue of Scientific Literature shows that these experiments are described in two papers bearing the titles "On the Sensitive State of Electrical Discharges through Rarefied Gases," Part I. (Phil. Trans., 1880, 170, 165-229), and "On the Sensitive State of Vacuum Discharges," Part II. (Phil. Trans., 1881, 171, 561-652). In the spacious days of forty years ago it was possible for a man of pre-eminent ability to secure election as a fellow of the Royal Society on what might now be regarded as a mere sample of the scientific work of which he was capable. Under these conditions Lord Moulton's election in 1880 was a natural sequel to his partnership with Spottiswoode, following upon his earlier record as Senior Wrangler and Smith's prizeman. His greatest service to science was, however, undoubtedly the whole-hearted co-ordination of chemical enterprise which he brought about during the war, and then strove to perpetuate in time of peace.

Lord Moulton was educated at Kingswood School, and maintained his interest in the school to the end. During the first year after the Armistice he took part as an old boy in the annual dinner, which had been allowed to lapse during the war, and also distributed the prizes at the school where his first academic success had been won. A Moulton scholarship founded by his son will perpetuate his association with the school, and a scheme is already in progress for supplementing this by a stained-glass window in the chapel recently erected as a war memorial.

Our Bookshelf.

Effects of Winds and of Barometric Pressures on the Great Lakes. By John F. Hayford. (Publication 317). Pp. v+133+16 plates. (Washington: Carnegie Institution, 1922.) 2.75 dollars.

THIS book records what is probably the most complete investigation yet made of the effect of winds and atmospheric pressure on the slope of the surface of great sheets of water. It deals with Lakes Erie and Michigan, which are large and of fairly irregular outline and bed-contour, and are situated in a region where the meteorological conditions are well observed. Continuous records of water-level are afforded by several gauges on each lake, designed to smooth out the local wave-fluctuations. Mr. Hayford has constructed an elaborate theory connecting the daily change of level of the water surface, as revealed by each of these gauges, with the north and west components of barometric gradient on the current and preceding days; proportionality factors, varying with the station, are derived by the method of least squares from large numbers of observations. The winds, being more rapidly variable than the barometric gradient, are considered from hour to hour; the hourly change of level at any gauge station is related to the hourly changes in the values of a certain function of the wind-velocity during the hour in question and the following hour; the said function is derived partly by theoretical reasoning. The numerical constants of the theory have been worked out in great detail, in order that the real changes of content of the lakes may be derived from the gauge-readings with sufficient accuracy to enable the evaporation from the surface to be estimated in varying circumstances.

British Meteorological and Magnetic Year Book, 1920. Part III. Section 2. *Geophysical Journal*, 1920. (Air Ministry: Meteorological Office.) *il.* 5*s.*

THIS publication comprises the daily values of the meteorological and geophysical elements at three observatories of the Meteorological Office, namely, Kew Observatory, Richmond; Valencia Observatory in Ireland; and Eskdalemuir Observatory, Dumfriesshire; and at the St. Louis Observatory in Jersey: daily values of solar radiation at South Kensington; wind components at fixed hours at four anemograph stations; tabulations of occasional soundings of the upper air; and results of observations of cloud and aurora. The annual supplement contains upper air temperatures by means of soundings with registering balloons and aeroplane ascents, giving monthly and annual averages with averages for the period 1917–1920; notes on seismological work at Eskdalemuir Observatory; the water-level recorder at Kew Observatory; and tables of monthly means of magnetic and electrical data for Eskdalemuir and Richmond respectively.

The introduction to the volume gives all details and necessary references to the actual data here brought together, following, in most cases, the arrangement of former years. It is to be noted that the soundings with pilot balloons and temperature determinations by means of aeroplanes will be discontinued, as these data now appear in the Daily Weather report.

The volume, like its predecessors, forms a valuable contribution to the study of the meteorological and geophysical elements, and the homogeneous nature of the data will be thoroughly appreciated by those who utilise the information.

The British Journal Photographic Almanac and Photographer's Daily Companion, 1923. Edited by George E. Brown. Sixty-second issue. Pp. 808. (London: H. Greenwood and Co., Ltd., 1922.) Paper, 2*s.* net; Cloth, 3*s.* net.

IT is a matter for congratulation that the abatement in the cost of printing papers has allowed of the use of paper of a quality superior to that which had to be employed for some of the preceding volumes of the Almanac. The arrangement of the matter is the same as heretofore. The Editor takes for the subject of his special article "What Camera and Lens to have," and hopes that those who are asked for advice on the subject will refer their questioners to it, and so provide a full answer and save their own time. Besides the calendar, which gives the public holidays in more than thirty different countries, there is a directory of Photographic Societies and other bodies, giving much information concerning each. The Epitome of Progress is the largest section, and the items are well classified and indexed. The usual statistical matter, photographic formulæ, and tables of all sorts, complete a most useful, practical and up-to-date reference book.

Proceedings of the Aristotelian Society. New Series, Vol. 22: Containing the Papers read before the Society during the Forty-third Session, 1921–1922. Pp. ii+242. (London: Williams and Norgate, 1922.) 25*s.* net.

THE volume contains the papers of the Session 1921–1922, abstracts of which have appeared from time to time in our Society notices. It reflects the great interest aroused by the discussion of relativity problems. Einstein's theory is the subject of a symposium to which Prof. Wildon Carr, Prof. T. P. Nunn, Prof. A. N. Whitehead, and Dr. Wrinch contribute. We may also direct attention to two papers, one by Prof. Johnstone on "The Limitations of a Knowledge of Nature," and one by Mr. Tavani on "Physical Space and Hyperspaces," both of which are of special scientific interest.

The Supremacy of Spirit. By C. A. Richardson. Pp. viii+159. (London: Kegan Paul and Co., Ltd., 1922.) 5*s.* net.

MR. RICHARDSON in this short volume sets forth, in clear and concise terms, the philosophical theory which he expounded in his "Spiritual Pluralism" in order to show its relation to the new psychology and its bearing on the somewhat dubious methods and even more elusive facts of psychical research. He states the case for psychical research, in its claim to be a purely scientific investigation, as well as it can be stated, but the argument is too brief to deal at all adequately with the scientific objections, those which are completely free from prejudice.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Spectrum of Neutral Helium.

In a letter to NATURE of November 25, p. 700, concerning my first communication (NATURE, August 19) on this subject, Prof. Raman expresses the opinion that the representation of helium lines derived from my assumption of the mutual apathy of the two interatomic electrons has a purely arithmetical character and would thus be deprived of any "real physical basis."

Disregarding a number of remarks reducible to the laceration of the empirically established series, a regrettable feature pointed out by myself (*Astrophys. Journ.*, September 1922), it will be enough to reply here to Prof. Raman's chief and apparently strongest objections. These are two: first, that the numerous coincidences yielded by my formula are simply explicable as so many "fortuitous arithmetical coincidences," and, second, that the particular value (109723) of the Rydberg constant N used in that formula is, in general, inadmissible, this value belonging legitimately to He^+, with a single electron, but not to the neutral atom with its two electrons.

Now it so happens that precisely these two points have steadily occupied my attention since the formula was first published, and I am therefore able to reply to both of them without delay. The corresponding details of reasoning and numerical data being all given in a paper just communicated to the American Physical Society (for its Boston meeting, December 27-29), to which readers may be referred, it will suffice to describe here the bare results.

1. Consider only those lines for which the final quantum numbers lie between 3 and 8, and the initial ones between 4 and 20, which fall within the interval $\nu = 17{,}000$ to 37,850. The total number of such distinct lines is $n = 680$. Among these there are $k = 45$ lines covering observed helium lines, with a mean deviation $|\delta\nu| = 2{\cdot}57$. In the considered ν-interval there are in all 97 observed lines. Whence, the mean (geometric) probability of hitting an observed line in a single trial by mere chance, $p = 0{\cdot}0182$, and the probability P of hitting k or more such lines in n (680) trials, by Bernoulli's theorem, $P = 1 - \Theta(x)$, where $\Theta(x)$ is the error-function and

$$x = \frac{\Delta}{\sqrt{2p(1-p)n}}, \qquad \Delta = |k - pn|.$$

In our case $pn = 12{\cdot}40$, $\Delta = 32{\cdot}60$, and therefore the probability that our set of 45 coincidences should be "fortuitous" is

$$P = 1 - \Theta(6{\cdot}61),$$

which is a little less than $1{\cdot}7 \cdot 10^{-13}$—small enough to discard every suggestion of the play of blind chance. This conclusion is considerably strengthened when other groups of coincidences tabulated in the *Astrophys. Journal* are similarly treated.

Of particular interest, in this and other respects, are the 18 lines of the type $\left(\frac{m_1 \cdot m_2}{4 \cdot 8}\right)$, and another group of three lines, each of the type $\left(\frac{5 \cdot m}{4 \cdot 4}\right)$ and each covering an empirical "combination" line of the "doublet system."

2. Let m be the mass of each of the two electrons, M that of the nucleus, and $\epsilon = m/M$. Taking account of the wobbling of the nucleus, through which the otherwise indifferent electrons perturb each other indirectly, and rejecting terms in ϵ^2, etc., the energy of the system in any stationary state, say $n_1 = \iota$, $n_2 = \kappa$, is found with comparative ease. This divided by ch gives the corresponding "term," say $T_{\iota\kappa}$, our ν being the difference of two such terms. If this be written

$$T_{\iota\kappa} = 4N_{\iota\kappa}\left(\frac{1}{\iota^2} + \frac{1}{\kappa^2}\right),$$

then $N_{\iota\kappa}$, the "Rydberg constant" belonging to the particular pair $(\iota\kappa)$ of electronic orbits, is a certain symmetrical function of the integers ι, κ, and of the mutual orientation of the two orbits. For the case of quasi-circular orbits (*i.e.* such as would become circular for $\epsilon = 0$ or no wobbling) the investigation given in the Boston paper leads to the interesting result

$$N_{\iota\kappa} = N_\infty\left[1 - \epsilon - \epsilon\gamma\frac{\iota^6 + \kappa^6}{(\iota^2+\kappa^2)\iota^2\kappa^2}\right], \quad . \quad . \quad (1)$$

where N_∞ (about 109737) is the constant for $M/m = \infty$, and γ the time-average of the cosine of the angle between the radii vectores of the two trabants. This formula holds for any inclination (i) of the two orbits and for any phase difference (α) of the two electrons describing them.

Now, a purely kinematical reasoning gives for $\iota \neq \kappa$ the value $\gamma = 0$, and for $\iota = \kappa$,

$$\gamma = \gamma_{\kappa\kappa} = \tfrac{1}{2}\cos\alpha(1 + \cos i), \quad . \quad . \quad . \quad (2)$$

where α is the angular distance of one electron from the ascending node when the other electron just passes through it.

Since for $\iota = \kappa$ the arithmetical expression in (1) becomes equal to unity, we have

$$N_{\kappa\kappa} = N_\infty[1 - \epsilon - \epsilon\gamma_{\kappa\kappa}], \quad . \quad . \quad . \quad (1a)$$

which, by (2), can assume any value from N_∞ down to $N_\infty(1-2\epsilon)$, with $N_\infty(1-\epsilon)$, the desirable He^+ value, just in the middle of the interval. If, *e.g.*, the orbits are coplanar and $\alpha = 180°$, we have $N_{\kappa\kappa} = N_\infty$, for then there is no wobbling; if $\alpha = 0$, $N_{\kappa\kappa}$ would reach the other extreme value, about 109709, and for $\alpha = 90°$ we should have the mean value (109723), which might even be made the only value if the lines of the type $\iota = \kappa$ are not to be very broad. There is thus no essential difficulty. Moreover, very few among my tabulated lines have $\iota = \kappa$.

For the overwhelming majority of those lines we have $\iota \neq \kappa$, when γ vanishes, and (1) becomes, no matter what the inclination of the orbits and the phase difference of the electrons,

$$N_{\iota\kappa} = N_\infty(1 - \epsilon), \quad . \quad . \quad . \quad . \quad (1b)$$

which is precisely the value (109722 to 23) used in my formula. This in itself seems to be a strong support for that formula.

LUDWIK SILBERSTEIN.

December 6.

Returning to my letter of December 6, I beg to supplement the same by a result of my last week's work, which seems to give the proposed theory a much stronger support than all probability estimates, for it represents *in toto* and orderly some empirical series of helium. In fact, guided by a few coherent items of my original table, I find that the whole *diffuse series of singlets*, denoted by $1P - m\mathrm{D}$, is represented by

$$\nu = 4N\left(\frac{18 \cdot 2n}{20 \cdot 4}\right) \equiv N\left(\frac{9 \cdot n}{10 \cdot 2}\right),$$

two final and one initial quantum numbers being

fixed. The other initial number $2n$ being given the successive values 6, 8, etc., or

$$n = 3, 4, \ldots 14,$$

the formula gives, with N = 109721·6, all the twelve observed members of the series from $m = 2$ to $m = 13$, respectively, the first with a deviation of 5, the second within 0·7, and the remaining ten members within a fraction, ranging from 0·1 to 0·35 Å.U.

The possibility of reducing 4N to N, based on the fact that all numbers are even, is interesting, especially as it forces itself on us also in the case of the fundamental and the principal series of singlets, which, though less precisely but again orderly and without gaps, are represented by

$$\nu = 4N\binom{2n}{6} - N\binom{n}{3}, \quad n = 4, 5,$$

and

$$\nu = 4N\left(\frac{14 \cdot 2n}{8 \cdot 4}\right) \equiv N\left(\frac{7 \cdot n}{4 \cdot 2}\right), \quad n = 3, 4, 5, \ldots 14.$$

This reducibility (to *one* N), if interpreted physically, would mean that the helium nucleus attracts each of its electrons with only one-half of its total charge, as if its lines of force formed two bundles, each entirely engaged with one of the two trabants. Details concerning these three series and the last-mentioned possibility will be given at the coming Boston meeting of the American Association.

Echinoderm Larvæ and their Bearing on Classification.

MAY I ask your permission for a short space in which to reply to Dr. Mortensen's letter published in NATURE of December 16, p. 806, under the title "Echinoderm Larvæ and their bearing on Classification." The points which Dr. Mortensen raises are two—namely (*a*) whether the Echinoderm metamorphosis is a metagenesis, *i.e.* an alternation of generations, or not, and (*b*) whether the fixed stage in the life-history of Asteroidea is a reminiscence of an ancestral condition or a secondary modification of development. I shall deal with the second point first. Dr. Mortensen states:

(1) That the group Spinulosa among Asteroidea are not primitive but modified forms and that the Paxillosa are the more primitive group, and that in this view certain modern systematists whom he quotes agree with him.

(2) That since the Astropectinidæ (Paxillosa) do not have a Brachiolaria stage in their ontogeny, this stage is not primitive and ancestral but secondarily intercalated where it occurs in the development of Spinulosa and Forcipulata.

I must confess that I am unconvinced by Dr. Mortensen's arguments. In his original work, reviewed by Dr. Bather, he forgot that the Brachiolaria larva was found in Spinulosa but referred it to Forcipulata only.

The systematists whom he quotes are neither palæontologists nor physiologists but—for the most part—students of the external features of preserved specimens only. Koehler (one of them) regards Hudsonaster, one of the oldest Asteroids known, as "voisine des Astropectinides," and W. K. Fisher also states that "typical Phanerozonia such as the Astropectinidæ are more primitive than the Spinulosa."

Now what these specialists are impressed by is the "phanerozonate" character of the Astropectinidæ, that is, the edging of the arms with a series of broad plates termed the "marginals." I have always protested against regarding this feature as a primitive character and in this protest I have the support of the best British authority on fossil starfish, W. K. Spencer. The fact is, the apparent marginals of these ancient starfish are not homologous with the marginals of the modern Paxillosa at all but are the adambulacrals. Reasoning from imperfectly described fossils and superficially described modern forms has completely misled the older systematists.

Ludwig, whom Dr. Mortensen quotes, was a worthy pioneer in the knowledge of Echinoderms, but he belongs in all his thoughts and views to another epoch. His classification, for example, of the Holothuroidea into Actinopoda and Paractinopoda has been completely disposed of by modern embryological research. In my letter of a year ago, I gave physiological and anatomical reasons for regarding the Astropectinidæ as Asteroids secondarily modified for a life on sand. I can only express the doubt whether Dr. Mortensen could have regarded the Astropectinids as primitive if he had ever thoroughly dissected one.

With regard to the homology of the stalks of the Bracholaria larva of the Asteroid and the Pentacrinoid larva of Antedon, I should like to reiterate the following facts:

(1) The larvæ are, broadly speaking, comparable; in both there is a long præoral lobe, a ventral stomodæum, right and left posterior cœlomic sacs.

(2) In both forms there is a fixing ("sucking") disc formed at *precisely the same spot*, and in both the præoral lobe is converted into a stalk.

Is it not infinitely more probable that the precisely similar stage of fixation is an original and ancestral feature in both ontogenies, and not as Mortensen supposes, ancestral in the Crinoid and secondarily intercalated in the Asteroid ontogeny?

Of course, the subsequent metamorphosis is very different in the two cases—but this difference I have correlated with the adoption of different feeding habits by two sections of the primordial Echinoderm stem. I have the support of Mr. Tate Regan, based on his study of a widely different group, that what he calls "habitudinal differences" are the basis of all differential evolution.

With regard to the "metagenesis" of Echinoderm larvæ, Dr. Mortensen states that in one species of Ophiuroid the whole larval body is reproduced by the remnant of the ciliated apparatus cast off at metamorphosis. This case is certainly unique among Echinoderm larvæ and I cannot accept it until Dr. Mortensen brings forward better evidence. In any case, it will not, even if true, alter our views as to the significance of the larva. May I remind Dr. Mortensen that Antedon among Crinoids and Amphiura among Ophiuroids can both eject their entire alimentary viscera and reduce themselves to a framework of arms with a nervous centre and yet regenerate all that is lost? Finally, in Dr. Mortensen's appeal to Dr. Bather, he forgets that what Dr. Bather objected to was my fathering of Dr. Mortensen's views on him. My friend Dr. Bather and I are in substantial agreement in our views on Echinoderms.

E. W. MACBRIDE.

Royal College of Science, South Kensington,
London, S.W.7, December 18.

DR. MORTENSEN (NATURE, December 16, p. 806) says that ". . . since the larvæ of the more primitive Asteroids (the Phanerozonia) are devoid of a Brachiolaria stage, the sucking disc . . . must be a later specialised structure. . . ." Surely the statement is an error, and (even if it were true) the conclusion unjustified. The Phanerozonia of Sladen

includes eight families. One of these families, the Asteropectinidæ, contains species with non-attaching larvæ. Two other families (the Asterinidæ and the Gymnasteriidæ) have species with attaching larvæ (Asterina, *Q.J.M.S.*, 1896, and Porania, *Q.J.M.S.*, 1915). It is true that the Asterinidæ approach the Cryptozonia in some respects, but taken by itself this fact might rather lead us to look on the Asterinidæ as "primitive"—an annectant family between the two great orders of starfish. The Gymnasteriidæ are frankly Phanerozonate.

While Asteroid classification is admittedly perplexing, we are on fairly safe ground when dealing with the recognised families. At present it is known that members of five different starfish families (Gymnasteriidæ, Asterinidæ, Echinasteridæ, Solasteridæ, Asteriidæ) have attaching larvæ, while members of only one family (Asteropectinidæ) have larvæ without a sucker.

Dr. Mortensen's virtual narrowing down of Phanerozonia to Asteropectinidæ renders valueless his citations of Sladen, Ludwig, Hamann, and Gregory in support of the arguments in his letter. I yield to no one in appreciation of Dr. Mortensen's work, but even if the adult Asteropectinidæ were in some respects a primitive family (I believe the opposite), still to draw the conclusion which he says "inevitably" follows from this premise, in defiance of the direct data of comparative Asteroid ontogeny, not to speak of other considerations, would surely be one of those strangely naive misuses of the Recapitulation theory which have done much to obscure its essential truth.

Age and Area in Biology.

IN his recent book, "Age and Area," Dr. Willis gives (p. 114) the following: "Table showing in the horizontal lines the average number of vice-counties in Britain reached by the most widely distributed species in each genus of different sizes, and by the second, third, fourth, and fifth most widely distributed species."

	Average No. of vice-counties reached by the				
	1st sp.	2nd sp.	3rd sp.	4th sp.	5th sp.
Genus of over 10 sp. .	108	104	96	86	79
6-10 sp. .	103	84	64	49	33
5 sp. .	98	76	39	22	16
4 sp. .	89	61	35	13	..
3 sp. .	89	48	27	..	..
2 sp. .	73	33	..	..	..
1 sp. .	50	..	..	..	..

Dr. Willis is convinced that the only explanation of the gradual diminution in average distribution from top to bottom of the table is that the average age of the species in the upper rows is greater and that they owe their wider distribution to their age. The gradation can, however, be explained without the help of either the principle of "Age and Area" or that of "Size and Space," as will become obvious if the method of constructing the table be considered. The average distribution of all the species in each of Dr. Willis's classes, in part obtained from the table above and in part from the London Catalogue, tenth edition, proves to be as follows:

No. of spp. in Genus	over 10	10-6	5	4	3	2	1
Average No. of vice-counties reached	40	48	50·25	49·5	54·6	53	50

The averages thus vary somewhat irregularly. In taking the average of the most widely distributed species in the first class, more than 90 per cent. of the lower numbers are rejected, in the second more than 84 per cent. are rejected, in the third class 80 per cent., in the fourth 75 per cent., in the fifth 66 per cent., in the sixth 50 per cent., and in the seventh none at all. Naturally this changes an approximately equal set of numbers into a falling series.

It is now possible to deduce the converse of Dr. Willis's theorem; for by reversing his process and rejecting the higher numbers it can be shown that the age of the "youngest" species decreases with the size of the genus.

The average distribution in vice-counties of the *least* widely distributed species in each genus according to size of genus, in part from Dr. Willis's table and in part from the London Catalogue, is as follows:

No. of spp. in Genus	over 10	10-6	5	4	3	2	1
Average No. of vice-counties reached	3	5·4	16	13	27	33	50

The regularity continues for the next "youngest" species, as can be seen from the original table. In neither case would the regularity suffer if the vice-comital numbers were redistributed to the species by any random method, for the chance of a genus receiving both a very high and a very low number would increase proportionately with its size.

Merton, October 31.

Soaring Flight and the "Olfactory" Organs of Birds.

THE note on page 784 of NATURE, December 9, misses the point of the theory I wish to be tested. The theory is that the well-developed "olfactory" nerves and apparatus of those birds which are capable of soaring flight has the function, not of smell, but of a delicate tactile sense whereby the bird is able to detect and take instant advantage of those upward air currents which recent experiments with gliding machines have shown to be so important in soaring flight.

It has been shown by Darwin and others that vultures do not smell with their well-developed olfactory apparatus. The experiments referred to in NATURE of December 9 show that this nervous apparatus is not necessary to give the bird its homeward direction or to enable it to indulge in flapping flight. So well-developed an apparatus is almost sure to have some function. It is obvious that soaring birds are in constant need of a means to detect the direction and strength of wind currents, especially those in an upward direction, and to adjust their balance and their wings accordingly. When soaring, the eyes and bill of the bird are directed downwards and the mucosa of the nostrils is exposed to any upward currents of air. I think it very likely, therefore, that the well-developed "olfactory" apparatus of these birds is a mechanism for detecting the direction and quality of air currents, and that the central "olfactory" ganglia enable the requisite adjustments of balance and direction of wing and tail planes to be made. The fact that birds whose nostrils have been plugged have been able to fly home by flapping in no way contradicts this theory.

To test it, I suggest in the first place that the

sensibility of the olfactory mucosa should be abolished by painting with a 20 per cent. cocaine solution; and then see if a bird such as a gull can balance and soar as well after painting as before. Plugging of the nostrils, or section of the nerves, can also be tried. The effect to look for is on the capacity for soaring and gliding flight, not of flapping flight.

Nature Study and Phenology.

PHENOLOGY is the name given to that branch of meteorological science which has as its object the studied effect of weather conditions upon the seasonal development of animal and plant life.

From the late seventies of last century, and since 1891 on a uniform systematic plan, the Royal Meteorological Society has issued an annual report on phenology. This report, by collating and co-ordinating the work of a number of observers—mostly amateurs—in the British Isles, is able to present in summary form, supplemented by tables and maps, information of a most valuable botanical, ornithological, and agricultural nature.

Nevertheless, to accomplish such results, all that its observers are required to do is to note carefully the first appearance of certain birds and insects, twelve in number, and the first blooming of fourteen common plants. Other migrants and notes are asked for, but these are of secondary importance.

Here is a work which should surely appeal to the Nature-lover. By simply recording a few observations on a prescribed form, and forwarding the same promptly about November 15 (the close of the phenological year) to the Royal Meteorological Society, 49 Cromwell Road, S.W.7, the work of the amateur is lifted from a purely local value to become a real link in the progress of scientific research.

Stations are still urgently needed in many parts of our islands, and a copy of our observing form will be forwarded upon application to the office of the Society, or to one of us.

Water Snails and Liver Flukes.

IN connexion with the letter on the above subject in NATURE of November 25, p. 701, I should like to ask Dr. Monica Taylor if she has actual proof of sheep coming into contact with *Limnæa peregra*? The habitat of this species is so much more "watery" than that normally chosen by *L. truncatula* that it seems very doubtful if sheep could eat it with their food. Again, *L. truncatula* is such a widely distributed species that it seems difficult to believe that it is either rare in or absent from any district in which damp sedgy pastures are to be met with.

Planks left undisturbed for a few weeks, or cut rushes shaken over a newspaper after having lain on the ground for a time, might reveal the presence of *L. truncatula* in many places from which it was apparently absent. And what of *L. palustris*, the habits of which are often nearer to those of *L. truncatula* than *L. peregra*?

A. W. STELFOX.

National Museum, Dublin,
December 12.

REFERENCE to "The Life-History of the Liver Fluke," by A. P. Thomas (Q.J.M.S., 23, 1883), or indeed to almost any text-book in zoology, will show Mr. Stelfox that in order to become infected it is not necessary for sheep to eat the intermediate snail host of *Fasciola hepatica*. It suffices that the encysted cercariæ be swallowed. The latter may be found at considerable distances from their snail host; for the tailed cercariæ which give rise to the encysted forms exist as such for about a week after they have escaped from the host and are extremely active. On account of their microscopic character (they are just visible to the naked eye as snowy specks) the merest trace of water suffices for their needs. The more "watery" habitat of *L. peregra*, which is extremely common in all sorts of ditches, puddles, and streams, constitutes no impediment, therefore, to this snail acting as a disseminator of the liver-rot parasite granted that it can become properly infected. That it is capable of being infected and of setting free perfectly developed cercariæ I have abundant evidence.

In answer to my request for literature references to any host other than *L. truncatula* of the liver-rot parasite, Dr. Paul Pelseneer has kindly given me several, one of which (Lutz, *Centralbl. f. Bakteriol. und Parasitenk.*, xi. pp. 781-796, 1892), since it refers to *L. peregra* as an intermediate host of *Fasciola hepatica*, may be of use to Mr. Stelfox. With regard to the first of the methods of discovering *L. truncatula* suggested by Mr. Stelfox, I have had negative results in some districts although the sheep in these same districts are infected.

MONICA TAYLOR.

Notre Dame, Dowanhill, Glasgow,
December 16.

Effect of Moonlight on the Germination of Seeds.

DURING the summer of 1921 I investigated the effect of moonlight on the germination of seeds, and the results seemed to indicate a greatly increased velocity of germination. In order to determine whether this might be due to the effect of the moonlight on the diastase, a small quantity of mustard seed was crushed, and weighed quantities, after mixing with known amounts of water, were exposed to moonlight in Petrie dishes, controls set alongside being covered. Estimation with Fehling's solution of the sugar produced showed that there was an increased yield of about 15 per cent. caused by the moonlight.

A possible explanation of these results is to be found in the fact that at certain periods moonlight is plane-polarised, and in order to test this suggestion the experiments with crushed mustard seed were repeated with daylight after polarisation, either by reflection or by a Nicol prism. Control experiments were also carried out both in darkness and in ordinary daylight. The temperature was the same for all three experiments in each case and lay between 10° and 18°. A remarkable increase in the amount of hydrolysis was always noted when polarised light was used. Similar results were obtained with fresh oats, wheat, and cornflour, to which diastase had been added.

The investigation of this phenomenon is now being continued at Liverpool in conjunction with Prof. E. C. C. Baly and Prof. J. McLean Thompson, and the results already obtained are worthy of record since they give strong support. Diastase is added to a suspension of freshly prepared starch and the mixture well shaken. A drop of the mixture is placed on three slides under microscopes, one

being exposed to polarised light, one to ordinary light, the third being kept in darkness. After thirty to sixty minutes, depending on the strength of the diastase, rapid hydrolysis can be seen to take place on the slides exposed to polarised light, while in the two controls the starch granules remain almost intact for some hours. By the use of a delicate thermocouple, the temperature was proved to be the same in all three cases. When the light is intense, the starch granules in the case of the polarised light break down entirely to little masses of dextrin and crystals of sugar which give deposits of cuprous oxide on warming with Fehling's solution. These results have been obtained with potato starch and the endosperm of maize and of wheat, the latter without the addition of diastase if freshly prepared.

In view of the suggestiveness of these observations the investigation is now being extended in various directions, and I hope to communicate the results in due course. ELIZABETH SIDNEY SEMMENS.

Medical Education.

REFERRING to my letter (NATURE, December 9, p. 769), Prof. Dakin writes (NATURE, December 23, p. 845): "I am not quite clear whether this question has been propounded to invite answers, or to introduce another of Sir Archdall Reid's favourite discussions on mutations and fluctuations, etc." Prof. Dakin may rest assured that I do not invite a discussion about mutations and fluctuations. To be frank, I do not think such a discussion, conducted on purely scholastic lines, out of touch with reality, would be profitable. My object was simply to protest against the waste of time to which, as I supposed and still suppose, unhappy medical students are compelled. Here are some truths, none of which, I think, Prof. Dakin will deny categorically, but all of which, in practice if not in theory, are repudiated by many teachers of biology.

(1) Every relevant and verifiable fact, no matter how observed, is equal before science. Experiment is only one way—a very good way when need arises—of observing. The vast majority of authentic facts about living beings is derived from direct observation. People who limit their data to facts derived from experiment, or any other mode of observing, are, like those who insist on purely Christian, Mahomedan, or Hindoo testimony, merely sectarian. Dwelling in an islet of evidence they ignore the continent of truth which lies at hand.

(2) Our powers of observing are proportionate to our familiarity with the objects of study. Thus we can scarcely differentiate between peas in a pod or sheep in a flock; to an Englishman newly arrived in China all the natives seem much alike; but among our own kind, whom we study from birth to death, especially among our intimates, we see differences of every shade (*i.e.* fluctuations) between vital and enormous extremes—as, for example, in powers of resisting disease. Obviously, the experimenter who works among plants and lower animals knows nothing about fluctuations, and less than he ought to know about mutations. Lacking the necessary powers of observation, he merely guesses. That he guesses wrongly was abundantly demonstrated by my letter.

Can Prof. Dakin deny (*a*) that men, the only living beings minutely observable, are subject to stringent natural selection, (*b*) that this selection occurs amid fluctuations, (*c*) that evolution, proportionate to the length and severity of the selection, has resulted, (*d*) that human races never differentiate while there is interbreeding, but differentiate rapidly and invariably when separated by time and space, (*e*) that human races blend perfectly when crossed except in traits linked with sex, (*f*) that in spite of multitudinous human racial differentiations, there has never yet been recorded a useful human mutation, or one that changed the type of a race, (*g*) that human mutations (*e.g.* club-feet, idiocy, albinism) are not *inherited* independently, but are only *reproduced* independently, and (*h*) that lost ancestral traits never appear among natural varieties, but frequently among artificial varieties, even when purely bred.

Unless a biologist is able (1) to accept the foregoing propositions, or (2) to disprove them, or (3) to demonstrate that man is outside the scheme of Nature, he is not competent to teach biology to medical students; for, after these students leave him, they will observe for themselves, and be taught by men who have observed, with a minuteness and accuracy impossible to workers among plants and lower animals, and the things they then learn will be directly contrary to the teachings of the biologist.

I have before me the synopsis of instruction in biology of the Royal Colleges of Physicians and Surgeons. I must admit that it is a vast improvement, chiefly by way of elimination, of the rubbish (for a medical man) that I was taught as a student and which I supposed was still taught. The syllabus for 1923 will be even shorter and better. Biology, which should make doctors, in their vast numbers, the most potent scientific influence in the community, is disappearing from the curriculum. But I observe that the student must still learn the general structure of the Hydra and Lumbricus, the general structure and elementary physiology of Scyllium and Rana, and the elementary facts of evolution, heredity, and variation. But of what use, as taught by biologists, can these subjects be to the medical student? What, for example, will he learn about evolution, heredity, and variation? Will he learn that some characters are "innate," and the rest "acquired"? Recently I spent eighteen months trying to find out what biologists meant by these words and none could tell. Will he learn from a Lamarckian teacher that acquired characters are inherited, or from a neo-Darwinian that they are not? I spent a like period in trying to find out what was meant by "inherited," and failed again. Will he learn from a Darwinian that fluctuations furnish the materials for evolution? Or from a Mutationist that only mutations do so? Or will he be presented with such statements as the following: "The standard deviation of a coefficient of correlation computed from data derived from classes, members of which are mutually correlated, with special reference to the case of fraternal and parental correlations calculated from entries of siblings"? Will any biologist tell him that every character is a product of the combined action of nature and nurture (that is, is equally innate and acquired), that the human being is of such a nature that he is especially responsive to the nurture of use, and that this peculiarity bestows on man his position in the scale of life and has made him the educable and therefore, according to the teaching he receives, the rational animal—able to learn, for example, sense or nonsense concerning biology.

Breeding Places and Migrations of the Eel.

By Dr. JOHS. SCHMIDT, Copenhagen.

IN an article in NATURE ten years ago (August 22, 1912, p. 633) I gave a review of the position at that time of the question of the breeding grounds of the freshwater eel (*Anguilla vulgaris*). We had then been working for seven or eight years upon the question, and it was our intention to pursue the work further by means of investigations extending across the Atlantic.

In the ten years then following falls the period of the Great War. This rendered work at sea impossible. We managed, however, partly before and partly after the war, to carry out an investigation covering the greater part of the northern temperate waters of the Atlantic, and the question, Where does the eel breed? can now, in the main, be considered solved. At the same time, we have ascertained the duration and extent of the migrations of the eel-fry.

The previous investigations had been undertaken with the well-equipped research vessel *Thor*, but its radius of action would not suffice for transatlantic cruises. From 1913 until 1921, when the Danish Government acquired the mine-sweeper *Dana* to replace the *Thor*, we were obliged to make our investigations from ships without any special equipment for marine research, partly from various trading ships plying on transatlantic routes, and partly from two schooners kindly placed at our disposal by the owners (1913–1914, the *Margrethe*, 90 tons; 1920–21, the *Dana*, 550 tons).

I shall in the following give a brief survey of the discoveries made regarding the breeding places of the eel since my article in NATURE in 1912, adding also some remarks on the immigration of the eel-fry to Europe. For further details I must refer any readers interested to my recently published paper in the Philosophical Transactions.[1]

FIG. 1. European eel (*Anguilla vulgaris*). *Spawning places* (bounded by innermost 10 cm. curve); *distribution of larvæ* (dotted area) and of *adults* (black strip along the coasts where the eel occurs).

The curves show limits of occurrence; *i.e.* larvæ less than 25 mm. have only been found inside the 25 mm. curve, etc. The outermost curve denotes the limit of occurrence of unmetamorphosed larvæ (*nl*), 8 and 10 cm. (in the Baltic) of male eels and of eels less than 30 cm. in length. X: easternmost records of unpigmented elvers (Baltic and Mediterranean).

In my article in NATURE (August 22, 1912, p. 633) I summed up the position as follows: "We cannot say as yet where exactly the spawning takes place, and but little more than that the spawning places must lie in the Atlantic beyond the Continental Slope, and that they must be in the Northern Atlantic."

The smallest (youngest) developmental stage of the eel then known to us was a larva of 34 mm. length. In order to say anything definite as to where in the

[1] Philosophical Transactions of the Royal Society of London, Series B. No. 385, vol. 211, pp. 179-208, 1922.

Atlantic our eels did breed, we had to find far younger stages, for a larva so large as 34 mm. might well be imagined to have moved a great distance from the spot where it came into the world. Nor was it enough to find a few isolated specimens of the youngest stages; a spot which could be declared to be the site where the

FIG. 2.—Sizes of eel larvæ (*Anguilla vulgaris*) caught in a single haul of two hours' duration at *Dana* Station 871 (lat. 27° 15′ N., long. 61° 35′ W.) in the western Atlantic, June 27, 1920, depth about 50 metres. About 800 specimens of O-group and 1 of I-group are shown. A II-group specimen, length 74 mm., from the eastern Atlantic, is shown for comparison. Reduced to about one-quarter (see the centimetre-scale).

great hosts of eels from the European continent assemble for their spawning must necessarily yield earliest stages of the offspring in great numbers.

The task before us, then, was to chart the distribution of the various developmental stages of eel-larvæ, from the oldest, about 7½ cm. long—which we knew from previous investigations were to be found off the coasts of Western Europe and in the Mediterranean—to the earliest tiny stages which no one as yet had ever seen. If we could ascertain where, and at what seasons, these tiny larvæ were found, then we should at the same time have discovered *where* and *when* the eels spawn. Once it was known where the various sizes (age-groups) of growing larvæ occurred, it would be possible to form an idea as to the extent and duration of the migrations of the eel-fry from the breeding grounds to the fresh waters of Europe.

These years of research have been rich in excitement and suspense; disappointment alternating with encouraging discoveries, and periods of rapid progress with others during which the solution of the problem seemed wrapped in deeper darkness than ever. One is tempted to describe the investigations in their chronological sequence, from first to last, in order to show how by slow degrees, advancing step by step, we came to see great parts of the life-history of the eel emerge from the darkness that surrounded it. The question of space, however, precludes this. We must content ourselves with setting forth the facts as they now appear, after eighteen years of work, and seeing what conclusions may be drawn from them.

. . . . . .

The chart Fig. 1 gives us the main sum of these many years' investigations into the distribution of the eel larvæ. This may be briefly stated as follows: The larvæ of our European eel (*Anguilla vulgaris*) are found distributed across the whole of the Atlantic Ocean from off the coasts of Europe to those of the United States. They increase in number, but decrease in size, as we pass from the European side towards America. The curves on the chart show that the spawning grounds comprise a restricted area in the western Atlantic, north-east and north of the West Indies, between 65° and 48° long., for here—*and here only*—are the youngest, newly hatched larvæ found. The eel spawns at the close of the winter and during spring. In April the larvæ had an average length of 12–13 mm., in June 25, and in October 35–40 mm. During their first summer the larvæ are found only in the western Atlantic. Enormous quantities of these first-year larvæ (the O-group, as we call them) are found at this season west of 50° W. long. In June 1920, when we were working there with the schooner *Dana*, it was impossible to draw a net through the upper water layers without bringing them up in quantities, and we often took several hundred specimens at one haul, as shown in the illustration Fig. 2.

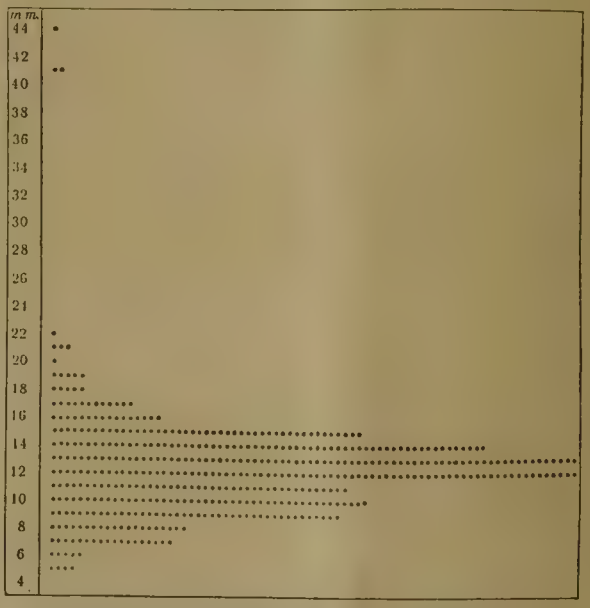

FIG. 3.—European eel (*Anguilla vulgaris*); western Atlantic (west of 50° long. W.), *Dana* Stations 935-948, April 1921; C-group and 3 specimens of I-group.

We are therefore excellently acquainted with the sizes and growth of the O-group larvæ. In June 1920 the four or five thousand specimens taken varied from 7 to 37 mm. in length, with an average of 25 mm.

In the course of the autumn and winter, the great bulk of the first-year larvæ (the O-group) disappears from the spawning grounds in the western Atlantic, but

a number of stragglers remain there throughout the winter, appearing in the following spring as a I-group, sharply distinguished in point of size from the young fry of the O-group which have come into being mean-

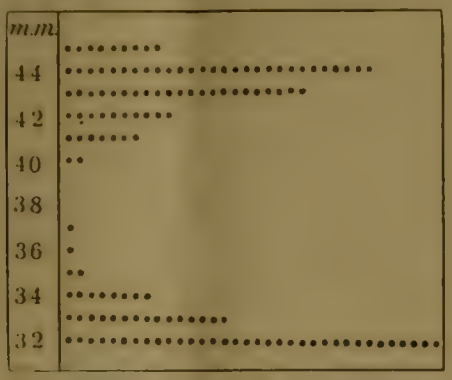

FIG. 4.—European eel (*Anguilla vulgaris*); western Atlantic (west of 50° long. W.). *Dana*, June 1920. Showing limit between O-group and I-group.

time (see Figs. 3 and 4). These specimens of the I-group, however, found in early summer west of 50° W. long., are comparatively few. The great majority, now measuring 50-60 mm., have, in the course of the winter, moved north-east and east, and are now in the central Atlantic, about as far as the longitude of the Azores, or even some distance farther east. In the following year again, by early summer, these larvæ have attained their full size, averaging about 75 mm., and appear now, as a II-group, off the western shores of Europe and far up in the Mediterranean, having, in the latter case, passed in through the Straits of Gibraltar during the winter, or in the autumn.

The retrograde metamorphosis of the full-grown larvæ takes place in the course of the autumn and winter. In the process, they become elvers, and in spring, being then three years old (the III-group) move up into fresh water, when the temperature of the latter permits. At this stage of development they resemble miniature eels (Fig. 5). The average length is about 65 mm., but they have lost greatly in dimensions and weight during metamorphosis, running no fewer than 1500 specimens to the pound. In England, it is more especially on the west coast, in the Bristol Channel, that the elvers ascend in very great quantities during the spring, the phenomenon being generally known among the inhabitants, who catch them for human consumption, or even for feeding pigs. The name "elver," too, comes from this part of the country. There are interesting accounts from Gloucester telling how, in March and April, fishermen stand in hundreds along the river banks, each with a hand net, fishing for elvers, and often making astonishingly large catches—a hundredweight of fish per man in one night. Bearing in mind the fact that 1500 elvers go to the pound weight, it will be realised that enormous quantities of eel fry must come in every year to the coasts of Europe from the Atlantic, numbers answering well to the great masses of tiny larvæ we found with the *Dana* on the breeding grounds of the eel in the western Atlantic. In 1920, 1921 and 1922, we found first-year larvæ (O-group) of the respective years on those grounds, but at this present time of writing (October 1922), none of these will yet have reached their destination, the fresh waters of Europe. Not until next spring (1923) will the fishermen of the Bristol Channel be able to catch elvers of the 1920 stock, which appeared in our nets in the western Atlantic in June 1920, and are shown in Fig. 2. And not until 2½ years from now—that is to say, in the spring of 1925—will the 1922-year class, specimens of which were taken by the *Dana* expedition about six months ago (April and May 1922) near Bermuda, make their entry into the Severn.

Moving eastward, then, across the Atlantic, the eel fry come to the shores of Europe, and it is natural that here they should be found in greatest numbers. It is here also, that the capture of them has developed into an actual industry, as for example, apart from the Bristol Channel, also at several places in the south-west of Ireland, but especially on the west coast of France and the northern shores of Spain.[2] They are taken here in tons, and the inhabitants have special names for them (*civelles* or *pibales* in France, and *angúlas* in Spain).

FIG. 5.—European eel (*Anguilla vulgaris*); showing the size of the four youngest year-classes (O-, I-, II-, and III-groups) in June; slightly enlarged: the top specimen measures 25 mm. in length.

It must not be imagined, however, that all the eel fry coming from the Atlantic will be stopped by the west coasts of Europe. Great numbers of them continue

[2] Also at some places in the western Mediterranean on the west coast of Italy, the elver fishery reaches the status of an industry in itself.

on their way—living semi-pelagically—to the eastward, until the metamorphosis is completed, and the small eel young have acquired a dark covering of pigment. In Northern Europe they move—by way of the Channel and round the north of Scotland—through into the North Sea and farther, *via* the Danish waters, to the western parts of the Baltic, where they have been found so far east as E. of Bornholm, at stages where the metamorphosis was not yet quite completed (Dr. A. C. Johansen, with the *Thor*), Fig. 1. In the northern parts of the Baltic, elvers are not known, or indeed any eels less than 20-30 cm., though the eel occurs right in to the innermost waters of that sea. The eels found in Finland are large females, and on the east coast of Sweden no males have been found north of lat. 57° 08′ (off Öland); see Fig. 1. This peculiar fact evidently answers to what we know from the great rivers, where the female eels generally move farther up into the higher reaches than the males.

The eel fry enter the Mediterranean at an early stage, as unmetamorphosed larvæ, most often not even having attained their full larval size, between one and a half and two years old. As unmetamorphosed larvæ they are found throughout the western basin, west of Italy, and at times, perhaps, still farther to the eastward. Even in the most easterly parts of the Mediterranean, an ascent of elvers takes place, these being transparent, and thus not having fully completed their metamorphosis. I have in this connexion received some information, with samples, from Mr. Geoffrey W. Paget, Director of Fisheries Investigations in Cairo. At a pumping station near Alexandria, where fresh water is pumped in large quantities into a channel leading direct to the sea, Mr. Paget found, on February 24, 1920, "that elvers were present in prodigious quantities, being unable to proceed further on account of the station. From this date—February 24—until April 15, fishing was practically continuous, and we transported over 5,000,000 elvers to the canal systems inland." Mr. Paget's observations are highly interesting, showing as they do that elvers which have not yet completed their metamorphosis can occur in such great quantities so far east as about 30° E. long. Together with observations from northern Europe, they give us a clear picture of the remarkable power of migration possessed by the eel fry. From the breeding grounds in the western Atlantic to the mouth of the Nile is a distance approaching 90 degrees of longitude, or one-fourth of the earth's circumference, and this distance is covered by the eel fry in the space of about three years. They may reach the Nile and the western Baltic before their metamorphosis is yet complete, and the greater part of the journey is made while they are still in the leaf-shaped larval stage. No other instance is known among fishes of a species requiring a quarter of the circumference of the globe to complete its life history, and larval migrations of such extent and duration as those of the eel are altogether unique in the animal kingdom.

Theories of Magnetism.

By Dr. A. E. Oxley.

MUCH attention has been devoted in recent years to theories of magnetism, and an interesting survey of the position of the subject is given in the report of a committee of the U.S. National Research Council issued by the National Academy of Sciences, Washington, in August last (vol. 3, part 3). It is difficult in a descriptive article of moderate length to present judicially the various views which have been advanced, but an attempt will here be made to do this, using the report referred to as a basis, and supplementing it with accounts of one or two advances not recorded therein.

Poisson in 1820 published a mathematical theory of magnetism which was based on Coulomb's inverse square law. He merely regarded magnetic substances as possessing positive and negative magnetic fluids which could be separated by the application of an external magnetic field resulting in the production of the magnetic effects as observed in bar magnets. This theory was eventually (1831) shown to be untenable by Faraday's discovery of the phenomenon of diamagnetism.

Ampère's theory (1825), based on Oersted's discovery (1820) of the magnetic effects of an electric current, may be regarded as the foundation of modern magnetic theories, though at that time the laws of electromagnetic induction were unknown. This theory led Weber (1854) to develop a theory which aimed at an explanation of the magnetic effects of bar magnets on the assumption that the molecules were *always* equivalent to miniature magnets, whether the substance were magnetised or not, the action of the external field being merely to align the miniature magnets along the direction of the applied field. No explanation of the phenomenon of hysteresis was given, however, until Maxwell ("Electricity and Magnetism," § 444) extended Weber's views and interpreted the more complicated hysteresis effects in terms of certain quasi-elastic forces.

The theory of Ewing (1890) enabled us to visualise the nature of these hypothetical controlling forces by attributing the sluggishness of the response to an applied field as due to the interaction between special groups of molecules. This gave a rough explanation of hysteresis effects in terms of the mutual actions between complex groups of molecular magnets, and accounted for the shape of the hysteresis loops, the coercive force and the retentivity of a ferro-magnetic substance like iron.

At the beginning of the present century, attempts were made by Voigt and J. J. Thomson to outline an electron theory of magnetism based on the magnetic effects of a moving electron, but it was not until the theory of paramagnetism and diamagnetism of Langevin appeared (1905) that a satisfactory interpretation of these phenomena was presented.

The classical researches of Curie (1895) had shown that substances could be divided into three groups as regards their magnetic properties under an external field. These are, (1) diamagnetic substances, which show a minute negative induced moment, practically independent of temperature; (2) paramagnetic sub-

stances, which show generally a larger and positive induced moment, varying inversely as the absolute temperature, and (3) ferro-magnetic substances, which show still larger positive magnetic moments, which vary with the temperature and external field in a complex way. In each case the total induced moment per gram of the substance, divided by the applied field, is called the specific susceptibility. On Langevin's theory, a molecule consists of a congeries of revolving positive and negative charges; if the total initial magnetic moment of these is zero, the substance is diamagnetic, if it is not zero, the substance is either paramagnetic or ferro-magnetic. The diamagnetic effect must exist in all matter, but is masked by the larger para- or ferro-magnetic effects in the latter case. Langevin's theory indicated that when there is no interaction between the molecules, the diamagnetic effect is independent of temperature, while the paramagnetic effect varies inversely as the absolute temperature in accordance with the Curie rules mentioned above. Langevin did not consider ferro-magnetism; this was done by Weiss.

These remarks hold only in so far as there is no appreciable mutual action between the molecules. In ferro-magnetic substances, such action is pronounced, and Weiss (1907) extended Langevin's theory by introducing an intrinsic molecular field to represent this mutual molecular interference. According to Weiss the molecular field has not necessarily a magnetic origin; it corresponds to the forces determining crystallisation, but for magnetic purposes it may be regarded as a magnetic field proportional to the intensity of magnetisation, and its value is then of the order 10^7 gauss. Weiss further showed that the energy of this field is a measure of the thermal change when, at the critical temperature, the substance passes from the ferro-magnetic to the paramagnetic state. The results obtained with magnetite above the critical temperature showed that Curie's rule of paramagnetism held but that the constant of proportionality had a series of different values over certain temperature ranges. These values were interpreted by Weiss as due to sudden changes of the molecular magnetic moment by a unit, the value of which was found to be $16{\cdot}4\times10^{-22}$ c.g.s.e.m.u. This is the Weiss magneton; its value has later been corrected to $18{\cdot}54\times10^{-22}$. Weiss and others claim that this unit exists in many ferro-magnetic substances and in paramagnetic salts, though in the latter substances the evidence is not quite so conclusive. Further practical and theoretical extensions of the work have been made by Weiss, Kunz, Honda, and Frivold, but lack of space prevents an extended account of these here.

Honda (1910) made an extensive examination of the variation of susceptibility of many elements with temperature, and concluded that, in general, the Curie rules did not hold. In 1914 he submitted that the magnetic moments of molecules were not constant but depended on the temperature, and that they exert forces on one another which hinder their lining up parallel to the field. In solids which are paramagnetic, the magnetic unit is a spherical group of molecules. This sphere becomes elongated in the ferro-magnetic state. A second theory due to Honda (1914) advocates a gyroscopic motion of the molecule to account for diamagnetism and paramagnetism. This is very similar to the theories of Gans (1910–1916). There appears to be no doubt that certain gyroscopic motions are involved, but more recent evidence (see below) indicates that these do not arise from *molecular* rotations but from a gyroscopic property of the *electron* itself, i.e., *the electron is a magneton*.

Certain departures from the Curie rules for paramagnetic crystals at low temperatures have been examined by Onnes, Oosterhuis, and others, and interpreted in terms of a molecular field in a manner similar to that of Weiss.

The variation of diamagnetism accompanying the transition from the liquid to the crystalline state has been investigated by the writer (1911–22), who found that organic compounds changed their specific susceptibility by a few per cent. The theoretical explanation of the results was obtained by including in the Langevin theory of diamagnetism a term depending on the *local* polarisation which determines a *local* molecular field. Weiss regarded his molecular field as uniform, but in the present case it must be of an alternating character as we pass from molecule to molecule of the crystal. It exists whether the substance is subjected to an external field or not, and distorts the electron orbits, producing a few per cent. change of specific susceptibility on crystallisation. It can be shown that (1) these local fields are of the same order of intensity as Weiss's field, namely, 10^7 gauss, (2) the energy of this field is a measure of the latent heat of fusion, (3) the existence of such a field would induce a magnetic double refraction which is comparable with the natural double refraction of crystals, (4) the change of volume on crystallisation is the magneto-striction effect of this molecular field, and (5) the energy of the local molecular field per unit volume represents the tensile strength of the crystal.

Thus it appears that in all crystalline media there are intense local fields, the linking up of which from molecule to molecule determines the rigidity of the crystal. We are not certain what is the true nature of the field; it is probably partly electrostatic and partly magnetic. That the magnetic forces are important in determining the distribution of the planes of cleavage in crystals has been emphasised by the writer (1920), a *uniform* magnetic field being capable of isolating the cleavages, *i.e.*, of distinguishing between an open or close packing of the molecules in certain directions.

The present position of magnetic theories is fascinating. There appears to be evidence that the ultimate magnetic particle is neither the molecule nor the atom but the electron itself; in other words, the electron is not merely an electrostatic charge but also a magnetic doublet or magneton. Such a structure no doubt accounts for the spiral tracks of the β-particles as observed by C. T. R. Wilson. The problem of the interaction between such doublets in crystalline media is far from being solved. It appears that a useful picture of the mechanism is obtained on the Lewis-Langmuir theory (elaborated by Langmuir in 1919) of the cubical atom. In non-ionised media the coupling force between atoms is formed by units, each consisting of a pair of electrons, and each pair corresponds to a single valency bond of chemistry. The influence of

magnetic forces in determining crystalline structure, magne-crystallic action, and chemical combination in non-ionised media is apparent. It is interesting to note that Pascal (1910) showed that in organic compounds, all of which are diamagnetic, the molecular susceptibility is (apart from certain peculiarities of structure common to certain types of compounds) equal to the sum of the atomic susceptibilities of the component atoms. This is not true of ionised compounds, such as metallic salts, where the coupling between the atoms is probably of an electrostatic nature.

Further developments of the magneton theory were made by Parson (1915), who identified the electromagnetic coupling between pairs of magnetic doublets with the force of chemical combination. The magneton, or anchor ring electron, has been applied by Allen (1920) to interpret the phenomena of optical activity and optical isomerism. In connexion with the magnitude of the local magnetic field, namely, 10^7 gauss, it is interesting to note that Allen's calculations give a value 10^8 gauss at a distance from the anchor ring equal to its radius.

A number of attempts to obtain a quantum theory of magnetism have been made in recent years by Oosterhuis, Keesom, Gans, Reiche, and others. These are based on the assumption that the molecules are endowed with quantised molecular rotations, but the theory of Gans is the only one to take account of molecular interactions.

In connexion with these views the theory of Bohr and Sommerfeld must be considered. Though this has proved so successful in the interpretation of the fine structure of spectral lines, it does not appear at all obvious how the open elliptical orbits of this theory can give the uniquely balanced systems required to explain diamagnetism, nor does it give a picture of the directed forces which are responsible for crystal lattices. These considerations suggest that the atom must have a static structure. Perhaps the electron itself is quantised, the motion of its parts being highly localised compared with atomic dimensions. The electrons in an atom may be distributed on spherical or ellipsoidal surfaces, and the passage from one surface to another determine the emission of a definite amount of radiation of a certain frequency.

Quite recently Whittaker (1922) has published a new quantum mechanism of the atom based upon the existence of a number of atomic magnetic doublets. If an electron collides with this system the collision is perfectly elastic if the velocity of the electron is less than a certain amount. If the velocity exceeds this amount the electron passes through the magnetic system and hands over to the latter a definite quantum of energy which is identified as Planck's quantum. The derivation of the Balmer series can be obtained from this conception; it may later be found equally effective in interpreting the fine structure of spectral lines. Allen has replaced the particular magnetic structure postulated by Whittaker by a pair of ring electrons, thus identifying Whittaker's model more closely with Langmuir's cubical atom. The atomic structure is dynamical locally but is essentially static at ranges comparable with molecular dimensions. The static structure is required to account for crystalline and magnetic properties of matter in the non-radiating state. Recent experiments by the writer (1922) indicate that the occlusion of hydrogen by palladium produces a system the electronic configuration of which is similar to that of silver, and the fall in paramagnetism of the palladium is consistent with this view, silver being diamagnetic. Manganese which has been fused in an atmosphere of hydrogen is ferro-magnetic, although pure manganese is paramagnetic. Iron which has been fused in hydrogen has a higher coercive force than ordinary iron (like cobalt). These experiments indicate that when hydrogen is occluded in one of these elements an electronic system is produced corresponding to an element the atomic number of which is one higher than that of the element occluding the hydrogen. The suggestion is that the hydrogen electron, in such systems, enters into the outer shell of electrons of the metallic atom.

A static model, consistent of course with a highly localised dynamical model, such as the one advocated above, seems to be the only satisfactory interpretation of these results.

Obituary.

Prof. Oscar Hertwig.

THE death of Oscar Hertwig, formerly professor of anatomy in the University of Berlin and director of its Anatomical-Biological Institute, removes from the scene one of the chief leaders in morphological science. He formed a link in that chain of illustrious men including Johannes Müller, Gegenbaur, Fürbringer, and Gaupp, which has demonstrated how fully Germany has realised the importance of entrusting its great chairs of anatomy to men who are anatomists in the broadest sense of the word, leaders in vertebrate morphology and not merely experts in the details of anthropotomy.

Hertwig was most widely known through his series of admirable text-books. His "Lehrbuch der Entwicklungsgeschichte des Menschen und der Wirbeltiere" made its appearance in 1886 and has passed through numerous editions, both in its extended and in its condensed form ("Elemente," 3rd Edition, 1920). "Die Zelle und die Gewebe," first published in 1893, and known in its later editions as the "Allgemeine Biologie," is still widely used as a most admirable text-book of general biology on a cytological basis. During the years 1901–6 Hertwig brought out the various instalments of that wonderful encyclopædia which bears the characteristically German title "Handbuch der Entwicklungslehre der Wirbeltiere," edited and in parts written by himself. While it is, perhaps, permissible to hope that the appearance of this colossal work marks the approaching end of what may be called the encyclopædic age of biology, in which real progress has become more and more impeded and slowed down by the accumulation of minute details, there can be no question regard-

ing the value and utility of Hertwig's great "handbook."

Hertwig, a laboratory worker rather than a field naturalist, had no belief in "das schon morsch gewordene Lehrgebäude des Darwinismus," and to this fact we owe the last of his larger text-books—the useful and interesting, if not wholly convincing, "Das Werden der Organismen," first published in 1916 and now in its third edition.

Oscar Hertwig's really great, indeed epoch-making, contributions to the development of biological science are to be found, however, not in his text-books, but in a comparatively small group of original investigations, some of them carried out in co-operation with his brother Richard, which are of the most fundamental importance. It was in 1875 that Hertwig, forestalling van Beneden by a few months, showed for the first time, by his studies upon sea-urchin eggs, what was the real nature of the fertilisation of the animal egg—that the process consisted essentially of the fusion between the nucleus of the egg and the nucleus of one single spermatozoon. In 1878 there appeared the monograph by the brothers Hertwig upon the sense organs and nervous system of the medusæ—a work published before its time and perhaps destined to fill its rôle more completely in the future with a fuller recognition of the fact that the most fundamental function of the nervous system is to preserve intact the organic continuity in the animal body throughout its evolutionary increase in bulk.

In the early eighties of last century, Oscar and Richard Hertwig, stimulated by the work of English morphologists—Huxley, Lankester, and Balfour—turned themselves to the investigation of the foundations of the germ-layer theory, clearing up the muddle which had resulted from the non-recognition of what we now know by Hertwig's name, mesenchyme, and corroborating and amplifying Lankester's conception of the enterocœlic nature of the cœlom.

In 1890 Oscar Hertwig published his comparison of "Egg- and Sperm-formation in Ascaris," in which he worked out in minute detail the parallelism in gametogenesis in the two sexes, and cleared up the mystery of the "polar bodies," long known as characteristic of the unfertilised animal egg. Hertwig showed that male and female gametes are alike formed in sets of four, but that in the female sex three of each four degenerate, the three degenerate eggs being the polar bodies.

The last of Hertwig's works that demands mention is his study of those extraordinary malformations of vertebrate embryos to which he applied the name "spina bifida." In these the body of the embryo is divided into two halves by a longitudinal cleft traversing the notochord and the greater part of the central nervous system, and yet this seemingly irreparable injury proves no insuperable barrier to continued development. In many cases the cleft closes, the two halves unite and a perfectly normal individual results. Hertwig correlated these monstrosities with a hypothetical evolutionary stage in which the neural surface of the ancestral vertebrate was traversed by a slit-like primitive mouth, and to-day this is still the only working hypothesis at our disposal to explain a very extraordinary phenomenon.

It must not be imagined that Hertwig's activities were limited to such fields as are indicated by the various works to which allusion has been made. He interested himself in the social questions of the day, and the very last of his publications that has come into the writer's hands is "Der Staat als Organismus" (1922), with a trenchant criticism of some of those forms of extremism that are so rife at the present time.

Mr. A. Trevor-Battye.

Mr. A. Trevor-Battye, who died at Las Palmas on December 20, was an accomplished naturalist and Arctic traveller. The second son of the Rev. W. Wilberforce Battye, he was born in 1855 and adopted in 1890 the additional surname of Trevor on succeeding to certain estates that had fallen to his father. After leaving Oxford, Mr. Trevor-Battye indulged his taste for natural history in extensive travels in North America, Africa, the Himalayas, and Arctic Europe. In 1894, in the yacht *Saxon*, he visited the little known island of Kolguev, in the Barents Sea, with the object of devoting the summer to the study of its bird life. The *Saxon*, on returning from a cruise to Novaya Zemlya, missed Mr. Trevor-Battye through inability to reach the east coast, and returned to England without him or his companion, Mr. Hyland. The two Englishmen joined a party of wandering Samoyedes and made good their retreat to the mainland by sledge and boat. This was a fruitful expedition and completed the exploration of Kolguev.

In 1896 Mr. Trevor-Battye returned to the Arctic regions, accompanying Sir Martin Conway as naturalist on his expedition to Spitsbergen. Mr. Trevor-Battye made explorations around Dickson Bay and, with Prof. Garwood, climbed Hornsunds Tind. A few years later he visited Crete and made valuable contributions to the knowledge of its natural history.

Mr. Trevor-Battye was editor of natural history in the "Victoria History of the Counties of England," and of Lord Lilford's book on British birds. His own works included "Icebound on Kolguev" (1895); "A Northern Highway of the Tsar" (1897); and "Camping in Crete" (1913). "Crete: its scenery and natural features" was a recent contribution to the *Geographical Journal* (September 1919).

Dr. Fridolin Krasser.

A few weeks ago Dr. Fridolin Krasser was found dead in his laboratory at the Deutsche Technische Hochschule at Prague, where for several years he had occupied the chair of botany. He was widely known as a palæobotanist who had devoted himself to the investigation of Mesozoic floras, more especially to the study of the large collections of Upper Triassic plants from the well-known Lunz beds in the Hof Museum of Vienna. In 1887, Dr. Krasser published a note on heterophylly inspired by the work of Baron Ettingshausen, with whom he was closely associated. In 1891 he wrote on the Rhætic floras of Persia; a few years later he turned his attention to the Cretaceous plants of Moravia, and in 1900 and 1905 made some interesting contributions to our knowledge of Palæozoic and Mesozoic floras of the Far East.

Dr. Krasser published several papers on Upper Triassic floras, and it was hoped that he would eventually produce an adequately illustrated account of this important but still very imperfectly known period of botanical history. It would be a fitting recognition of the value of Dr. Krasser's work if the authorities of the Vienna Museum could see their way to entrust the material to which he was devoting his vacations to some palæo-botanical colleague with a view to the publication of a comprehensive memoir. Among other contributions reference may be made to papers on the genus Williamsonia and other Jurassic plants from Sardinia.

Dr. Krasser was a man of attractive personality, a good friend, and an enthusiastic investigator.

Prof. Rhys Davids.

By the death on December 27, in the fulness of years and honour, of Prof. T. W. Rhys Davids, England has lost a great oriental scholar. Son of a Congregational pastor at Colchester, and born on May 12, 1843, Prof. Davids was educated at Brighton School, and studied Greek and Sanskrit at Breslau University. He spent eight years in the Ceylon Civil Service, where he mastered Pali and commenced his Buddhistic studies. Returning home he became, from 1882 to 1912, professor of Pali and Buddhist literature at University College, London, and from 1904 to 1915 professor of comparative religion at the University of Manchester. He was secretary and librarian of the Royal Asiatic Society from 1885 to 1904, and he shared in the foundation of the British Academy, of which he was a fellow.

Prof. and Mrs. Rhys Davids—the latter also an accomplished Pali scholar—were the leading agents in spreading a knowledge of Buddhism in this country. An inspiring teacher and an indefatigable worker, he produced a number of books on the subject which he had made his own; the best known of which are his manual of "Buddhism," "Buddhist India," and "American Lectures on Buddhism." He also did good work in establishing the Oriental Translations Fund and the Indian Text Series. His death leaves a gap in the scanty ranks of oriental scholars which will not be easily filled.

We regret to announce the death on December 30, in his sixty-sixth year, of Dr. J. B. Haycraft, emeritus professor of physiology in the University of Wales.

Current Topics and Events.

Scientific workers are too well acquainted with the value placed on their services to be surprised at an advertisement for a university assistant lecturer in a department of science at a salary of 300*l.* a year. Recently, however, such an offer provoked an indignant protest from a disinterested member of the general public, who stated to us that the remuneration of his chauffeur was on a more liberal scale. While it is true that any educated man with aspirations would prefer a university teaching post, with its vague promise of an interesting and useful career, to the more mundane occupation, it is nevertheless a matter of the gravest concern that those educational institutions which are engaged in the task of increasing and disseminating knowledge are in such a parlous financial position that they are forced to offer salaries bearing no relation to the status of the posts, and imposing on their holders an unfair burden of financial sacrifice. The greatest benefactors of the universities are still the members of the teaching staffs themselves.

The story of Shackleton's last Antarctic expedition on the *Quest*, as presented at the New Scala Theatre, is a little disappointing, inasmuch as considerable interesting material is not explained. It is a difficult task for Commander Frank Wild to supply anything more than a running commentary with so much film shown. The curtailment of some of the "Departure" film and "Ports of Call" film, such as a bull fight in Portugal, all of which occupy considerable time, would, perhaps, be advantageous, and the audience taken as quickly as possible to the lonely sub-Antarctic islands with their fascinating bird life—to South Georgia and its whaling industry, and to the southern ice fields. A few still pictures introduced here and there would afford the lecturer an opportunity of giving more information, which is badly needed, of the natural history pictures. The natural history films are extraordinarily interesting, and commence with a landing through the heavy surf on St. Paul's Rocks on the equator. In the midst of these small dangerous rocks there is a lagoon of wonderfully clear water, with many species of fish to be seen in its pellucid depths. The rocks provide a nesting place for hundreds of sea birds. Excellent films are shown of the rookeries of the great wanderer Albatross, the Cape hen, the giant petrel, the Gentoo penguin, and the sea elephant, all taken at South Georgia. Ascension Island provides a moving picture of a great rookery of terns. The lengthy film of the whaling industry in South Georgia is shown with the film running at high speed, commencing with the harpooning of the rorqual, or blue whale, and showing the whole process of "trying out." This film is full of interest and instruction, but, unhappily, bears eloquent testimony to the extermination of southern whales. Soon these rorquals and fin-back whales will become as scarce as the sperm and southern whalebone whale, if the industry is allowed to continue uncontrolled. Zavodovski Island, to the south of South Georgia, was next visited. This ice-covered, rock-bound, and forbidding island is the home of countless penguins. Round its coast are numbers of deep caves which belch forth dense sulphurous fumes. The three months spent in the ice pack with constant vigilance and toil in battling the floes, are not of special interest from a lecture point of view, though no doubt useful scientific data was collected.

The duration record in gliding established at the recent contests on the South Downs has already been broken in a rather sensational manner, and by another

Frenchman, Lt. Thoret. The event took place at Biskra in Algeria on Wednesday, January 3, and Lt. Thoret stayed in the air more than seven hours, from 9.3 A.M. till 4.4 P.M. It is interesting to note that the flight was carried out on an ordinary aeroplane in which the power had been shut off completely, and not in a specially designed glider. The loading was 3·8 lb. per square foot instead of 2·2 lb. per square foot as in the specially constructed gliders used during the summer. The machine was a Hanriot 14 biplane, weighing 1364 lb. including a motor of 80 H.P.

APPLICATIONS are invited for the Theresa Seessel Research Fellowship of Yale University, value 300*l.*, for the promotion of original research in biological studies. Preference will be given to candidates who have already obtained their doctorate, and demonstrated by their work their fitness to carry on successfully original research work of a high order. The holder must reside in New Haven during the college year, October to June. Applications, which should be accompanied by reprints of scientific publications and letters of recommendation, and a statement of the particular problem which the candidate expects to investigate, should be made to the Dean of the Graduate School, New Haven, Conn., before May 1 next.

A SPECIAL meeting of the Royal Society of Medicine will be held on Friday, January 26, at 8.30, to commemorate the centenary of the death of Edward Jenner. There will be an address by Sir W. Hale-White on "Jenner and his Work," and objects of historical interest will be shown.

THE Trueman Wood lecture of the Royal Society of Arts will be delivered by Sir William Bragg at the Society's house, Adelphi, at 8 o'clock on Wednesday, January 24. The subject will be "The New Methods of Crystal Analysis, and their Bearing on Pure and Applied Science."

A NEW section of the Royal Microscopical Society has been formed for the purpose of dealing with the practical use of the microscope in connexion with industrial research. The inaugural meeting of the section will be held at 20 Hanover Square, W.1, on Wednesday, January 24, at 7 o'clock.

THE following free public Gresham lectures will be delivered at Gresham College, Basinghall Street, at 6 o'clock, on the dates named:—Physic, by Sir Robert Armstrong-Jones (January 23, 24, 25, and 26); Astronomy, by Mr. A. R. Hinks (January 30, 31, and February 1 and 2); Geometry, by Mr. W. H. Wagstaff (February 6, 7, 8, and 9).

THE Silvanus Thompson Memorial Lecture will be delivered at the Technical College, Leonard Street, E.C.2, on Thursday, February 1, at 7.30 P.M., by Sir Oliver Lodge, who will take as his subject "The Basis of Wireless Communication." The chair will be taken by Sir Charles Parsons. After the lecture a conversazione and re-union of old students will be held. A collection of Prof. Thompson's paintings and apparatus will be shown and a number of demonstrations will be given in the laboratories.

A COMMITTEE, consisting of representatives of the Institutions of Mechanical Engineers and Naval Architects, has been appointed with the object of carrying out tests on oil engines and of reporting on the performance of motor-driven vessels. The Engineer-in-Chief of the Fleet has, with the approval of the Admiralty, joined this committee. In scope, the proposed trials will include economy and thermodynamic tests ashore and manœuvring tests at sea. Wherever possible the behaviour of the propellers and the hull will be examined. It is intended to test engines of as many representative types as possible. The first actual testing work will probably be carried out about April next.

THE National Institute of Agricultural Botany is now accepting entries for its second series of yield and quality trials of new varieties of potatoes from breeders who are willing to entrust the Institute with the marketing of their productions on a profit-sharing basis. The trials are planned to last for five years, at first in Scotland only, but in the later years also in the English potato districts. Only those varieties which do sufficiently well in the trials will be placed on the market. Full particulars of the conditions of the trials can be obtained from the Secretary, N.I.A.B., Huntingdon Road, Cambridge, to whom those intending to enter new varieties for these trials should apply not later than February 28.

WE have received a copy of the programme, rules, and regulations of the International Exhibition for Photography, Optics, and Cinematography, which is to be held at Turin during next May and June in the Newspaper Palace at the Valentino Park, under the initiative of the Board of Trade and Industry at Turin, and under the high patronage of H.M. the King of Italy. The photography section is divided into seven classes, and each class into several sub-classes. Photography in general, optical projection, photomechanical methods, photography in its application to science, photographic materials and literature, are all included. The optical section includes optical glass, machinery for making lenses, prisms, etc., spectacles of all sorts and oculists' apparatus, microscopes, telescopes, opera glasses, optical instruments in general, bibliography, and schools. The cinematography section is similarly classified. Applications to exhibit must be made on forms that will be supplied and which must arrive, duly filled in, not later than March 1 at the General Commissary, Via Ospedale, 26, Turin (the head office of the executive committee.)

THE character of the primitive Crustacean limb was disputed between Mr. E. W. Shann and our reviewer in our issue of December 2 (p. 736). In fairness to the former, a statement of the present state of knowledge seems called for. It is now generally held by the leading authorities that Trilobites represent the ancestral group from which Crustacea were derived. All investigated species of these appear to have had biramous limbs, while some of the most primitive had the posterior region of the body relatively soft and uncalcified, and were in process of evolution

from Annelids. Hence if the Apodidæ (and all other Crustacea) arose from Trilobites possessing biramous limbs, their own foliaceous appendages must be presumed to be derived from the biramous type, notwithstanding the similarity of their structure to the foliaceous uniramous parapodia of some Annelids. It is possible that the bilobed type of parapodium possessed by many Annelids may have given rise to the biramous Crustacean limb. On the other hand there is the objection felt by a few that the descent of the Apodidæ and other Crustacea from an ancestral group of Trilobites does not necessarily follow from the fact that Trilobites are the earliest known Crustacea. The Apodidæ themselves have many structural affinities with Annelids. Thus it is conceivable that the Crustacean-Annelid may have produced divergent branches of which the Trilobites (biramous-limbed) represent one, and the Apodidæ (foliaceous-limbed) the other. This view, however, is not regarded with favour by the chief authorities.

AT the sitting of the French Academy of Sciences held on October 23, 1922, a note was presented by MM. Constantin, Joessel, and Daloz "concerning a boat which travels against the wind while using the wind itself for motive power." An article on the same topic, entitled "Un bateau paradoxal," appears in *La Nature* of November 11. An ordinary sailing-boat cannot use the wind for directions which are too near that directly opposite to the wind, and it was long ago suggested that if an arrangement like the sails of a windmill were substituted for ordinary sails, the boat could travel even against the wind. Napoleon was urged to use this as a means of surprising the British fleet. Scientific work on the idea was initiated in 1901 by Constantin, who constructed a model car on wheels which advanced against a current of air blown on it. The publication of Drzwiecki's theory of propellers in 1909 encouraged Constantin to proceed further. He attracted the attention and approval of many French men of science, and a syndicate was formed for the development of the method, but the war interrupted the work. In 1917 work was resumed, and since then the idea has been applied successfully. Joessel (son of the well-known investigator in aerodynamics) put an air-screw—like the sails of a windmill—of 5 metres diameter into a 2-ton sloop, *La Drésinette*, connected with a marine propeller of 60 cm. diameter, and successful journeys were made on the Erdre, near Nantes, and on the Loire. This was in 1918. Later on a 9-metre air-screw was installed in the 5-ton boat *Bois Rosé*, connected with a marine propeller of 105 cm. diameter, and on September 15, 1922, this boat sailed successfully on the Seine, between Saint Cloud and Sèvres, in all winds and against the wind, without causing any derangement in the ordinary traffic. It was estimated that the speed was 2 metres per second against a wind of 7 metres per second. The investigations were conducted with the help of the French *Direction des recherches scientifiques et industrielles et des inventions.*

Our Astronomical Column.

THE PLANET MERCURY.—This planet reaches its easterly elongation on January 13 and will be favourably placed for naked-eye observation at about that date.

The best time to obtain a glimpse of the planet will be at about an hour after sunset, when it may be seen at a low altitude over the west-south-west horizon. The planet may be expected to be about as bright as a first magnitude star would appear in a similar position and involved in twilight. Mercury does not shine with the same steady light as some of the larger planets, but often exhibits a sparkling fitful lustre.

Being rarely visible owing to its proximity to the sun, it is necessary for intending observers to look for the planet at special periods like the present, when its apparent elongations from the sun enable it to be perceived with the unaided eye.

THE JANUARY METEORS.—A brilliant full moon and passing clouds somewhat interfered with observation of this event. The maximum display was expected on January 3, and Mr. W. F. Denning writes that at Bristol fine meteors were visible occasionally, and indications were that had the conditions been favourable, the shower would have been fairly conspicuous and plentiful.

At Stowmarket, Miss A. Grace Cook and Mr. J. P. M. Prentice obtained independent observations on the night mentioned, and remarked some fine meteors from the usual point of radiation at 232° +52°.

The sky was not watched after midnight and the maximum seemed to have been attained in the earlier part of the evening. Miss Cook recorded bright meteors from the special shower of Quadrantids at $6^h\ 58^m$, $8^h\ 10^m$, $8^h\ 43^m$ and $10^h\ 18^m$, and there were others of about mag. 1. At $9^h\ 36^m$ there was a fireball from the direction of Aquarius.

On the night of January 4, the shower of Quadrantids seemed to have become nearly extinct. At $8^h\ 48^m$, however, Miss Cook witnessed the appearance of a remarkable stationary meteor. It was as bright as Venus, and shone for about $1\frac{1}{2}$ seconds with a motionless aspect at the position 222° +77°. There is a known shower at this point in Ursa Minor and it corresponds with the point of radiation of Mechain-Tuttle's Comet on December 20.

COMING SOLAR ECLIPSES.—The eclipse of September 10, 1923, will be total in California and Mexico. The sun's altitude will be more than 60°, and the duration of totality $3\frac{1}{2}$ minutes. The weather prospects are very hopeful. There is little doubt that the Einstein problem will again be studied. Mr. F. Slocum (*Astr. Journ.* No. 809) gives a list of the stars within $2\frac{1}{2}°$ of the sun's centre down to mag. 9·0. They are mostly faint, especially those nearer the sun, and it will need skilled photography to record them. It is proposed to photograph a check field, some 5° distant, on the same plates during totality, thus giving an independent determination of scale value, and enabling the whole Einstein displacement to be utilised. Otherwise much of it is lost, only the differential shift being available.

The succeeding totality, on January 24, 1925, crosses the north-eastern states. Four observatories —Vassar, Yale, Van Vlack, and Nantucket—enjoy total eclipse; its duration is $1\frac{1}{2}$ minutes, but the sun's altitude is less than 20°. The star field is better than that of 1923 but not so good as 1919.

Research Items.

THE PILOU FEAST IN NEW CALEDONIA.—A valuable account of the festival known in New Caledonia as *Pilou*, a word which seems to mean "repetition, rhythm," in connexion with the ritual dances forming a leading part of the ceremonial, is given in *L'Anthropologie* (vol. xxxii. Nos. 3-4) by M. Maurice Leenhardt. The object of this elaborate series of dances and ritual seems to be the periodical expulsion of evil spirits and other dangers, which has been fully discussed by Sir James Frazer in "The Golden Bough," 3rd ed., The Scapegoat, chaps. iii. iv. This article, fully illustrated by drawings and photographs, deserves the attention of anthropologists.

PENCIL PIGMENTS IN WRITING.—In the issue of *Discovery* for January, Mr. C. Ainsworth Mitchell discusses the question of the identification of pencil pigments in writing. He shows that the microscopical appearance of lead and its alloys is quite distinct from that of graphite, the lines showing a disconnected series of patches irregularly distributed, uniformly and brilliantly lit up, and each patch is marked with regular vertical striations. Writing in different pencil pigments may sometimes be differentiated by chemical tests. For example, the graphite and clay used for the pigment frequently contain very varying amounts of iron or of chlorides, and the markings with them show reactions of different intensities when tested with the respective reagents. Titanium is also a common constituent of natural graphites, but seldom sufficient to give a distinct reaction in the markings on paper. In that case, however, a colour test alone was sufficient to distinguish the marks made with that pencil as compared with others examined.

GLANDS OF THE MICRODRILI.—Dr. J. Stephenson (Trans. R. Soc. Edin., liii. pp. 241-265, 1 plate, 1922) has investigated the septal and pharyngeal glands of the four families of Microdrili (Oligochæta)—Tubificidæ, Enchytraeidæ, Naididæ, and Lumbriculidæ. In the anterior segments are numerous deeply staining cells associated with the blood vessels, muscular strands, septa (forming the "septal glands"), body-wall, and pharynx and œsophagus (forming the "pharyngeal glands"). Only in the Enchytraeidæ do the cells discharge into the lumen of the pharynx; their products—largely disintegration products—penetrate between the cells of the dorsal wall of the pharynx. In none of the species examined do cell processes of the "glands" penetrate the alimentary wall. The cells (except in the case of the Enchytraeidæ) appear to constitute ductless glands and their secretion mixes with the coelomic fluid. The cells arise from the peritoneal lining of the coelom and not from the alimentary epithelium.

OOSPORE FORMATION IN PHYTOPHTHORA.—A note of considerable interest to mycologists is contributed by S. F. Ashby to the *Kew Bulletin* (No. 9, 1922, pp. 257-261) upon the formation of oospores in a species of Phytophthora, *P. Faberi* Maubl. The author has isolated from the cacao plant in Jamaica and Grenada, from rotting cotton bolls in St. Vincent, and from the coconut palm in Jamaica, strains of Phytophthora, apparently this species, which appear identical in growth in pure culture save that the strain from cacao seems less vigorous. In pure cultures oospores are not formed upon any of these strains, but if the strain from cacao is grown in mixed culture with either of the other two strains, oospores appear regularly in the culture as the mycelia interpenetrate and persistent antheridia are present. So far these interesting observations would admit of interpretation upon the assumption of heterothallism so thoroughly worked out by Blakeslee for the Mucoraceæ, but Ashby's observations upon the result of mixing strains of this species with a strain of the distinct species *P. parasitica* Dast. isolated from Ricinus in India are totally unexpected. Oospores are developed in such mixed cultures but are throughout of the diameter characteristic of *P. Faberi*, the smaller oospores of *P. parasitica* not being detected. The further development of this interesting work will be followed with great interest.

PHILIPPINE EARTHQUAKES.—We have received a reprint of the *Weather Bulletin* (for December 1920) of the U.S. Weather Bureau containing the catalogue of Philippine earthquakes for the year 1920. The number of shocks recorded (147) is close to the average (150) for the last eighteen years, though only one (the Benguet earthquake of October 8) was strong enough to cause slight damage to buildings. In two useful tables are given the monthly numbers of earthquakes felt in the Philippines for every year from 1903 to 1920, and also similar numbers of earthquakes recorded at Manila, the total numbers being respectively 2699 and 5781. An interesting result obtained from these tables is that, as in other insular seismic districts, the earthquakes of the Philippines are subject to a very slightly marked annual period.

OIL IN RUSSIA.—Some aspects of the occurrence of oil in Russia formed the subject of a paper read by Mr. T. G. Madgwick before the Institute of Petroleum Technologists on December 12. The author considered briefly the geology and structures of the principal fields, and by a generalised correlation of these widely distributed occurrences, attempted to forecast the future possibilities of the country as an oil producer, both as regards existent and potential resources. While it may be doubted whether such prolific pools as those of Baku will ever be struck again (the conditions here being peculiarly favourable to oil accumulation), so much unprospected territory, at least technically favourable, remains to be examined, that he would be a bold man who prophesied a non-recurrence of industrial achievements which at one time rivalled even those of the United States. The cure for the present ills of the Russian petroleum industry lies in the establishment of political and economic stability, in reorganisation of existing fields, and in a business-like system of production. The author also stressed the necessity for giving serious attention to certain technical problems, in particular water troubles, which even before the Revolution were causing anxiety to many producers. Developments of existing fields may be expected in the Caucasus (Terek region), in the eastern end of the Apsheron peninsula, and in the lower part of the Kura river. The unknown factor, however, is unquestionablyTranscaspia; the Emba district, N.E. of the Caspian Sea, is already a producing field, but vast areas, at present almost inaccessible, await exploration, both to the east and north-east; these prospects have the added merit of being scientifically favourable, at all events in so far as our present geological knowledge of Asiatic Russia is concerned. The author left out of consideration the Sakhalin and Eastern Siberian prospects; these isolated occurrences are only imperfectly known and in any case they can have no relationship with the main resource-area under review; from the geological point of view, they are more closely allied to the occurrences in Japan, and may ultimately be expected to reveal similarities both in development and economic magnitude to that country.

ELECTRICAL DISTRIBUTION ON TWO SPHERICAL CONDUCTORS.—In a recent paper to the Physical Society Dr. Alexander Russell returns to the electrostatic problem of two spherical conductors. The most interesting feature of the investigation is the fact that Kelvin's method of images is not the best way to attack the problem. The author shows how Poisson's method can be made to yield useful results, amenable to easy and accurate numerical computation. The principle of the method is as follows. A functional form is postulated for the potential at any point of the actual but unknown electrical distribution on each sphere, and the constancy of the potential on each sphere is used, coupled with the theory of inverse points. The two cases, (1) one sphere inside the other and (2) the spheres outside one another, are discussed in detail, and applications are made to find the force between the spheres, the energy, and the stress in the medium.

AN AUTOMATIC VOLTAGE REGULATOR.—For electric lighting it is essential that the voltage of the dynamo should vary only between very narrow limits. In country house lighting where the direct current dynamo is driven by a petrol motor the voltage variations sometimes cause serious and very objectionable fluctuations of the light. Messrs. Isenthal and Co., Ltd., now manufacture an automatic rapid action voltage regulator suitable for use with dynamos up to 50 kilowatt capacity. The device is extremely simple, and by its use the voltage can be maintained practically constant even when the driving speed and the load vary very suddenly. The principle employed is practically the same as that used in other vibratory regulators some of which, the Tirrill regulator, for example, are extensively used in electric lighting stations. Messrs. Isenthal's regulator is, however, applicable to quite small machines, and should prove very useful.

GLIDING FLIGHT.—*Die Naturwissenschaften* of October 6, 1922, contains an article by Prof. C. Runge, of Göttingen, entitled "Uber den Segelflug," reproducing a lecture delivered at Wasserkuppe during the German gliding contests last August. Prof. Runge gives a clear account of the main principles underlying gliding or sailing flight. After emphasising the point that a steady horizontal wind is useless for the purpose, the author divides useful winds into two categories, (1) steady winds in upward directions, and (2) variable winds. The former can be used in gliding flight if the vertical component is at least equal to the rate of vertical fall of the glider, and Prof. Runge points out that upward winds are of frequent occurrence; that, in fact, ordinary air movements in the form of wind are primarily vertical, but are horizontal more or less to us because we live at that stratum of the atmosphere affected by the earth's solid crust. In the case of variable winds, several kinds of variations are possible: thus different air layers may have different speeds, or the air in any one layer may have different speeds at different times. An attempt is made to explain non-mathematically how such variation can be used for flight. The effect of dimensions is also considered briefly.

LOSS OF HEAT FROM SURFACES.—At the request of the Engineering Committee of the Food Investigation Board, Dr. E. Griffiths and Mr. A. H. Davis of the National Physical Laboratory have carried out a series of measurements to determine the laws of gain or loss of heat by solid surfaces in contact with air at temperatures which differed from their own, and the results are embodied in the recently issued Report No. 9 of the Board (H.M.S.O., price 1*s.* 6*d.*). It is shown that the loss or gain is mainly due to the convection currents set up in the air close to the surface, and that the amount of heat transmitted per unit time and area is proportional to the 5/4ths power of the difference of temperature of surface and air, a law first stated by Prof. L. Lorenz in 1881. Unfortunately the factor of proportionality is not independent of the shape, size, and orientation of the surface, the loss for the same difference of temperature being greater per unit area and time for a small surface than for a large, and for a horizontal surface facing upwards than for one facing downwards. The authors give curves from which the proper value of the factor can be obtained in any practical case, so that the Lorenz law may be readily used by heating, ventilating, and refrigerating engineers.

UPPER-AIR WINDS IN INDIA.—Memoirs of the Indian Meteorological Department, vol. xxiii. Pt. III., which has just reached us, contains mean monthly characters of upper-air winds deduced from the flights of pilot balloons at thirteen stations in India during the period 1910 to 1919. The discussion has been carried out by Mr. J. H. Field, director of the Agra Observatory, and is published under the direction of the Director-General of Observatories. It contains nearly 100 foolscap pages of figures, with two pages of explanation. At many of the stations the observations are for a few months only and it is not easy to select a period with consecutive observations at several stations. The stations are distributed fairly well over India. Good comparisons can be obtained for the greater part of 1919, and these observations show a general increase in the speed of the wind with height, which is greater in winter than in summer, although this varies with the latitude, being more marked in northern India, according to the observations in February and August at Lahore, Agra, and Akyáb, than in the south as shown by Bangalore. Naturally there is also much variation in the direction of the wind of the upper air at different seasons. To plot graphically the observations for the several stations for the several months and for varying heights would involve considerable labour, but where air-ways are to be used such plotting seems essential. The data will supply much which is of interest relative to the movement of the upper-air over India, and associated with what is known at the earth's surface, it will afford most useful and instructive information.

A NEW BECK MICROSCOPE.—Messrs. R. and J. Beck, Ltd., 68 Cornhill, E.C., have submitted to us an example of their Model 22 "London Microscope." The instrument is simple in design and is supported on a modified horse-shoe base with widespread limbs, which gives complete stability even in the horizontal position. The coarse adjustment is of the spiral rack and pinion pattern, the fine adjustment is of the vertical type with milled head. The stage is a large one measuring 4 in. × 3½ in. With one eye-piece, and a low-angled ⅔ in. and a ⅙ in. objectives in canvas-covered case, the price is the moderate one of 8*l.* 17*s.* 6*d.* Double or triple nose-pieces are supplied at an additional cost of 1*l.* 1*s.* and 1*l.* 10*s.* respectively. A spiral, screw focussing, swing-out condenser of the Abbe type with centring screws, cell, and iris diaphragm costs an additional 2*l.* 7*s.* 6*d.* The instrument is well made and thoroughly efficient and is suitable for all ordinary microscopical work. Additional objectives and other fittings can be supplied if desired.

Exhibition of Physical Apparatus.

TIMES have changed since Lord Bacon had to complain that "the mechanic, little solicitous about the investigation of truth, neither directs his attention nor applies his hand to anything that is not of service to his business." The modern "interpreter of Nature" would contribute scantily to the advancement of learning were he bereft of the mechanic's services, and it is by a happy thought, therefore, that the Physical and Optical Societies bring together every year the manufacturers and users of scientific instruments. At their thirteenth annual exhibition, held at the Imperial College of Science on January 3 and 4, such a wealth of beautiful, and in many cases novel, apparatus was to be seen that we can only refer to a few of the particularly interesting exhibits, selected somewhat arbitrarily.

Of special interest to engineers was a micro-indicator (Cambridge and Paul, Ltd.) for high-speed engines, in which the dimensions of the parts eliminate inertia-errors. A specially designed stylus cuts on celluloid a minute indicator-diagram which can be enlarged photographically or examined at once with a microscope. The Elverson oscilloscope (Herbert Kennedy and Co.) by intermittent illumination made a machine at 1500 revolutions appear to be either stationary or working at 150 revolutions, enabling faulty action to be detected and located. A fine adjustment for speeds derived from a phonic motor was shown in a strobometer (Tinsley and Co.), and comprises a friction gear providing an infinitely variable speed. A tapered drum driven from the phonic motor engages an axially movable friction wheel which carries contacts controlling the intermittent illumination of a stroboscopic disc or the like, the position of the wheel indicating the frequency of the illumination as a percentage of that of the tuning fork which governs the phonic motor.

Much interest was expressed in the new celluloid mirrors (Adam Hilger, Ltd.), the thickness of which is equal to a few wave-lengths of light. These were applied to vertical illumination in a microscope (an arc lamp failing to heat the celluloid on account of its thinness), to acoustic purposes in an optical sonometer, and to the transposition of colour combinations in patterns in the chromoscope (The Chromoscope Co.). In the latter apparatus each element of the design is prepared as a stencil for use in conjunction with a Wratten colour screen which can be changed at will, and by means of an optical device the various elements are viewed in superposition by transmitted light. Other novelties by Hilger were an interferometer attachment for calibrating microscope racks, indicating backlash, and checking the fit of the slide; and some ultra-violet spectrograms on the new Schumann plates which, with a minimum of gelatine and a fluorescent component in their emulsion, require a remarkably short exposure. The latest "Demonstrator's Lantern" (Newton and Co.) could be arranged at will for projecting ordinary slides, for opaque objects, for vertical projection, or for microscopic, polariscopic, or spectroscopic projection. Among microscope improvements might be noted a stand and sub-stage (R. and J. Beck, Ltd.) designed to prevent mechanical disturbances from causing the disappearance of objects from the field of view under high power. The enhanced resolving power obtained by the use of crossed Nicols was demonstrated with this instrument. A new saccharimeter (Bellingham and Stanley) exhibited several novel features. The polarising prism is constructed without the use of cement, the visible edge of the half-prism is a natural edge of the crystal, and the quartz plate, compounded of right- and left-handed quartz wedges, is within the size limit for which flawless crystals are obtainable.

An annual feature of the exhibition is the display of radium apparatus for medical and demonstration purposes by Mr. Harrison Glew. Every year it is a pleasure to see this pioneer, to whom suffering humanity owes no small debt. A radiological ionometer (Watson and Sons) comprised an ionisation chamber connected to an electroscope and arranged for measuring the precise X-ray dosage administered to a patient. Another medical instrument was that for estimating the carbon dioxide content of alveolar air (Cambridge and Paul). It employs a Shakespear katharometer, the thermal conductivity of a breath sample being compared electrically with that of pure moist air. The smoke nuisance received attention in Dr. E. A. Owen's automatic air filter and his jet apparatus (Casella and Co.). In the former, samples of air are strained through white filter paper at regular intervals, the dust content being estimated from the colour of the resulting deposit. In the jet apparatus, a jet of moist air impinging normally on a glass slip is found to deposit its dust, which can then be examined microscopically.

Of electrical testing apparatus there was an immense variety, from the high-frequency low-voltage Moullin voltmeter (Cambridge and Paul), which employs a triode valve so arranged as to preclude disturbance of the circuits to be measured, to the "Meg" insulation tester (Evershed and Vignoles, Ltd.), a remarkably light and cheap megger running to 10,000 mgo. which should prove a boon to linemen. A multiversal test set by Elliott Brothers claimed to measure milliamperes, kilovolts, capacities and much else, besides functioning in Varley and Murray loop tests. A novel relay for radio signals was that designed by Mr. Anson (Tinsley and Co.), in which a neon lamp in the anode circuit of a triode valve intensifies current variations on account of its negative characteristic.

Demonstrations of actual manufacturing processes were given by the Igranic Electric Co. (automatic winding of transformers) and Dallmeyer, Ltd. (lens-making shown by kinematograph); and examples of the daily work of the National Physical Laboratory aroused much interest. Each day Mr. W. Gamble lectured on the "Reproduction of Colour by Photographic Processes," an outstanding feature of his lecture being the projection of slides made by the new Eurochrome process, recently acquired from Germany by the Austrian State Printing Office. The results of this process, the nature of which is somewhat obscure, mark a substantial advance in the art. Prof. E. G. Coker lectured on "Recent Photo-Elastic Researches on Engineering Problems," giving a beautiful demonstration of his method, in which the distribution of stress in transparent models is traced by means of polarised light. In this way he showed the effect of shape on stress-distribution in chain links, tensile and compressional test specimens, and gear and worm wheels in action. He also demonstrated the stresses set up during turning, planing, and milling, showing that the cutting edge is preceded by a region of compression and followed by one of tension, the shaving itself being free from stress in the neighbourhood of its point of attachment. With a burred edge the stresses were seen to oscillate.

Mr. F. E. Smith, who made the necessary arrangements, is much to be congratulated on the success of the exhibition which failed to furnish any experimental evidence for the unluckiness of its number. Some fifty-six exhibitors participated. C. W. H.

Scientific Expeditionary Research.

A SMALL meeting, which was attended by representatives of several of the sciences more immediately concerned, was held in the rooms of the Linnean Society, on January 3, under the presidency of Sir Kenneth MacKenzie, Bart., to discuss the formation of a "Scientific Expeditionary Research Association"; and it was agreed that this action should be taken. The general objects of the scheme, as stated in a draft which had been prepared before the meeting, are to facilitate and promote scientific research by means of expeditions to all parts of the world. The association, which is to be precluded from making any distribution of dividends or bonus in money, is to consist of a body of fellows and members, and any profits which may accrue from its operations are to be devoted to the objects stated.

It is proposed to commence with an expedition to the Pacific, visiting islands which lie off the beaten track, and the journey is to be undertaken in a sailing ship. The necessary funds are to be provided by the contributions, at a fixed rate, of about fifty persons of either sex who may be expected to take a general interest in the work of a scientific expedition. A more definitely scientific nucleus is to be provided by the nomination, by scientific societies or in other ways, of from six to ten suitably qualified persons who would not be expected to make any contribution in money.

It is believed that the scientific members of the party would be able to carry out investigations during the cruise or at islands at which a halt was to be made, and that they would be able to interest and obtain assistance from the others. The itinerary, which would be decided beforehand, would be arranged so as to facilitate work of a serious nature, and the plan of the tour would be devised with special reference to the investigations it was proposed to carry out. This matter would be in the hands of an advisory council, in which it is hoped that it will be possible to include representatives of various sciences who could assist in drawing up a practicable scheme. It is believed that there would be a profit on the first cruise, and that this would be available for partly financing the next expedition, supplemented by receipts from other sources, such as the subscriptions of fellows and members, the profits of lectures and the sale of specimens and publications. The existence of an organisation which would be able to send out scientific expeditions as required, from time to time, would be likely to prove extremely useful in advancing natural knowledge.

The promoters of the scheme believe that they will have no difficulty in obtaining the support necessary to enable them to carry out their first expedition. If this can be done, it seems obvious that there should be many opportunities of obtaining valuable collections of animals, plants, and rock-specimens; and that the investigation of these collections is likely to yield results which will give the association the right to claim that a part of its objects has been accomplished. It was pointed out at the meeting that success in carrying out research-work during the cruise was likely to depend mainly on the possibility of finding qualified investigators who would be able to accompany the expedition, and of planning a tour which would give scope for the execution of the work on which they were severally engaged. The meeting can scarcely be said to have been in a position to decide how this could be done, and no definite scheme has at present been thought out. The difficulties were admitted, but the opinion was expressed by certain speakers that they could be surmounted, by the restriction of the efforts of each cruise to a series of investigations which would not be incompatible with one another.

The officers of the association are Sir J. Kenneth D. MacKenzie, Bart. (president), Commander D. Blair, R.N.R. (marine superintendent), and Mr. Frederick W. Kealey (organising secretary); and the offices are at 68 Pall Mall, S.W.1, from which further information can be obtained. Suggestions as to lines of work which could profitably be undertaken during the first cruise would be gladly received by the officers, and it is particularly desirable to receive the names of well-qualified scientific investigators who would be prepared, if appointed, to accompany the expedition and to carry out specified researches.

Geography in Education.

THREE matters of scientific interest were discussed at the annual meetings of the Geographical Association. Sir John Russell, of Rothamsted Experimental Station, gave the presidential address on "The Influence of Geographical Factors on the Agricultural Activities of a Population." Confining his illustrations to Britain, he pointed out that in earlier times each village community had to be self-supporting, and that agricultural systems were uniform all over the country. This implied that certain areas, mainly heavy clays and light sands, were perforce left vacant, and that the drier south and east were the most attractive for agriculture and settlement. With later improvements of transport and increased knowledge of how to combine animal production with the growing of grain and other vegetable foods, the action of the geographical factors was modified, and the modification seems now to be in process of being carried a step further, as different parts of the country are specialising in productions, mainly luxuries, for which they are specially suited.

Dr. Olive Wheeler, of the University of Manchester, spoke of "The Place of Geography in the Education of the Adolescent." She approached the matter from the point of view, not of subjects, but of the pupils. She considered specially the physical and mental development of young people between the ages of 12 and 16. She pointed to the quick growth in bulk and the rapidity of bodily changes, and emphasised also the extreme importance of the new emotional experiences, social, æsthetic, and religious, as well as sexual. Any education worth the name must take account of the fact that boys and girls of the ages considered are, consciously or unconsciously, attempting to find a philosophy of life. It is the business of teachers to arrange that the process is carried on with tolerance and broadmindedness. To do this it is necessary that education should deal with the study of matter on one hand and with the development of personality by means of the humane subjects on the other. Dr. Wheeler then emphasised again the position of geography as a correlating subject in which is considered not only how matter affected man but how man affected matter. Geography, probably, better than any other subject helped boys and girls to obtain a true philosophy of life.

Prof. Tower, American commercial attaché, American Embassy, lectured on "Geography in Business

Life." If Dr. Wheeler stressed the value of geography in living, Prof. Tower emphasised the value of geography in earning one's living, and gave examples. He referred to an institution in the United States, at which the finger of scorn was pointed because it took as its motto "Anything to catch the nimble nickel." It was significant that geography had been taught there for many years, is still being taught, and there is no suggestion that it should go out. Even more striking was the case of one of the great trade houses of New York—of international reputation—which looked for a trade adviser, not to get business himself but to help other heads of departments. They were advised by their chartered accountants to appoint a geographer as the most suitable man, and did so. Prof. Tower told also of a convention of eighty administrative heads of great business houses in the United States. In each of the last three years there have been discussions of the relations of geography teaching to trade and business, and most of the important geographers have contributed to the discussion. It is significant that this course was adopted by men who never were taught geography themselves as it is taught now, and knew only what modern teaching has done.

Mr. E. J. Bradford, of the University of Sheffield, read a paper at the annual meeting of the Geography Section of the Training College Association. The paper dealt with the results of a geography test given to various classes in secondary schools, and was noteworthy in that it was set neither by an external authority to pass or fail candidates nor by a teacher to find out what his pupils knew. The test was set for purely scientific objects. The methods bear some resemblance to those of intelligence tests, but were constructed with the view of finding, not the intelligence of the pupils but the effectiveness of the geography teaching from year to year. The results were extremely interesting, but admittedly the experiment is only in its initial stages, and it would not be fair to state the conclusions tentatively drawn, as they may be modified.

Paris Academy of Sciences.

PRIZE AWARDS FOR 1922.

AT the meeting of the Paris Academy of Sciences, held on December 18, the following prizes and grants for 1922 were awarded:

Mathematics.—The Grand prize of the Mathematical Sciences to Jean Le Roux for the whole of his work; the Poncelet prize to Jules Drach for the whole of his work in mathematics; the Francœur prize to Louis Antoine for his works on geometry.

Mechanics.—The Montyon prize to Farid Boulad; the Fourneyron prize to J. A. Farcot d'Albaret for his work on the gas engine; the Henri de Parville prize to Henri Béghin for his memoir on the theoretical study of gyrostatic compasses.

Astronomy.—The Lalande prize to Henry Norris Russell for his work in physical astronomy; the Valz prize to Jean Chazy for studies in celestial mechanics, and particularly for his memoir on the course of the movement in the problem of three bodies when the time increases indefinitely; the Janssen medal to Carl Störmer for his theoretical and experimental researches on the aurora borealis.

Geography.—The Delalande-Guérineau prize between Achille Lamotte and Charles Mailles (in equal parts); the Gay prize to Ludovic Gaurier for his explorations in the Pyrenees; the Binoux prize to Paul Le Cointe for his study of the river Amazon; no award was made of the Tchihatchef prize.

Navigation.—The prize of six thousand francs between Maurice Garnier (3000 francs) for his work on the calculation of trajectories by successive arcs, André Vinsot (1500 francs) for a contribution to the study of the tactics of loosing torpedoes, and Henri Roussilhe (1500 francs) for his hydrographical researches; the Plumey prize to Edouard Sauvage for his work on steam engines.

Physics.—The L. La Caze prize to Anatole Leduc for the whole of his scientific work; the Kastner-Boursault prize to Camille Gutton for his work in electricity, and more particularly on Hertzian waves; the Hébert prize to Charles Chéveneau for his work in electricity and magnetism; the Hughes prize to Camille Raveau for his work in various branches of theoretical physics; the Clément Felix foundation to Alexandre Dufour for the continuation of his researches on the registration of Hertzian waves.

Chemistry.—A Montyon prize (Unhealthy Trades) (2500 francs) to (the late) Charles Boulin for his researches on mustard gas; an honourable mention (1500 francs) to Louis Tampier for his work on the manufacture of poison gas; the Jecker prize between Marcel Godchot (5000 francs), Marc Bridel (2500 francs), and Georges Tanret (2500 francs) for the whole of their chemical work; the La Caze prize to Paul Thiébaud Muller for his physico-chemical researches; the Cahours foundation to Andrée Chaudun for her physico-chemical study on sugar inversion; the Houzeau prize to René Dubrisay for his work on solutions.

Mineralogy and Geology.—The Victor Raulin prize to Louis Longchambon for his researches on the relation between rotatory power and crystalline symmetry.

Botany.—The Desmazières prize to Edouard Chatton for his work on the Protozoa, Louis Emberger and Ethel Mellor receiving honourable mentions; the Montagne prize to Etienne Foëx for the whole of his work in mycology; the La Fons Mélicocq prize to Pierre Allorge for his memoir on the botanical geography of the French Vexim; the de Coincy prize to Marcel Denis for his work on the Euphorbiaceæ.

Anatomy and Zoology.—The Cuvier prize to René Koehler for his researches on the echinoderms; the Savigny foundation to Jacques Pellegrin for his memoir on the fresh-water fishes of Northern Africa; the Thore prize to Lucien Chopard for his work on the Orthoptera.

Medicine and Surgery.—Montyon prizes to Charles Dopter (2500 francs) for his book on meningococcic infection, Eugène Wollman (2500 francs) for his studies on life in the absence of micro-organisms, Edmond Lesné and Léon Binet (2500 francs) for their book on the normal and pathological physiology of the infant; honourable mentions (1500 francs) to Emile Weil and Jean Loiseleur for their works on pneumo-serous diagnoses and therapeutics, J. B. Piot-Bey for his work on the organisation and working of the veterinary service of the state domains of Egypt, and Philippe Lasseur and Louis Spillman for their book on antibody reactions, a quantitative study of the fixation of alexine; citations to André Feil for his memoir on the absence and diminution of the cervical vertebræ, to Serge Tchahotine for his researches on experimental cytology made with the microscopic radio-puncture method, to Maurice Fontoynont and Humbert Boucher for their contribution to the study of the mycoses of Madagascar; the Barbier prize to Edmond Delorme for his work on pulmonary decortication; the Bréant prize between

Marie Phisalix, for her book on poisonous animals and their venoms, and Edmond and Étienne Sergent, for their work on the etiology and prophylaxy of Debab, a trypanosomiasis of the dromedary of Northern Africa; the Godard prize to Jean Turchini for his studies on the cytological processes of elimination of colouring matters by the kidney; the Mège prize to Pierre Mathieu for his researches in experimental physiology; the Bellion prize between Giuseppe Favaro (700 francs), for his book "Lo spatium supra-genuale e le formazioni in esso contenute," and Arthur Vernes (700 francs), for his researches on the measurement of flocculation by photometry; the Baron Larrey prize to Pierre Perrin de Brinchambaut for his book on the criteria of aptitude for flight in aeroplanes.

Physiology.—The Montyon prize to Gaston Giraud for his memoir on medio-cubital association in wounds of the upper member; the La Caze prize to Léon Fredericq for the whole of his work in physiology; the Pourat prize to René Wurmser for his memoir on researches on chlorophyll assimilation; the Martin-Damourette prize to Pierre Abrami for his researches on the pathogeny and treatment of marsh fevers; the Philipeaux prize to Costantino Gorini for his studies on the lactic fermentation.

Statistics.—The Montyon prize to Pierre Richard for his work on the mathematical theory of assurance.

History and Philosophy of Science.—The Binoux prize to Gino Loria for his historical works.

Medals.—The Berthelot medal to Charles Boulin, Marcel Godchot, Marc Bridel, Paul Thiébaud Muller, René Dubrisay.

General Prizes.—The Alhumbert prize to Charles Mauguin for his work on liquid crystals; the Bordin prize to Joseph Magrou for his memoir on symbiosis and tuber formation; the Lallemand prize to Paul Wintrebert for his work on the nervous systems of embryonic vertebrates; the Vaillant prize to Wladimir Vernadsky for the whole of his work in mineralogical chemistry; the Houllevigue prize to Rodolphe Soreau for his work on aviation and book on nomography; the Saintour prize to Serge Metalnikoff for his work in immunology; the Henri de Parville prize between Robert Lespieau (2000 francs), for his book on the chemical molecule, and Léon Toraude (500 francs), for his historical publications; the Lonchampt prize to Henri Colin for his work in plant physiology; the Henry Wilde prize to Carl Benedicks for his memoir on the homogeneous electro-thermic effect; the Caméré prize to Jules Bied for his researches on cement; the Victor Raulin prize between Philippe Schereschewsky and Philippe Wehrlé (1000 francs) for their memoir on cloud systems, and Augustin Boutaric (500 francs) for his work on the intensity of solar radiation; the Gustave Roux prize to Pierre Teilhard de Chardin for his work in palæontology; the Thorlet prize to Adolphe Richard.

Special Foundations.—The Lannelongue foundation between Mmes. Cusco and Rück; the Laplace prize to Louis Marcel Massenet; the medal is also accorded to eight other pupils of the École polytechnique; the L. E. Rivot prize between Louis Marcel Massenet, Louis Edmond Séraphin Charvet, Jacques Alexandre Morane, and Alexandre Georges Louis Delattre.

Funds for Scientific Research.—The Trémont foundation to Clément Codron for his book on cutting metals; the Gegner foundation (2000 francs) to Jules Geffroy; the Jérome Ponti foundation to Pierre Mahler for his work on combustibles; the Hirn foundation to Emile Schwoerer for his work in mechanics; the Henri Becquerel foundation to André Danjon for the application of his method of measuring the apparent diameter of the stars; the Charles Bouchard foundation to Georges Bohn for the continuation of his biological work; the Henry Le Chatelier foundation to Paul Riou, Ernest Toporescu, and Paul Mondain-Monval (5000 francs each) for researches bearing on the manufacture of sodium carbonate by the ammonia method, Pierre Lafon (5000 francs) for researches on the enamelling of iron.

University and Educational Intelligence.

THE United States Public Health Service has, in co-operation with the Bureau of Education, collected information as to the present status of sex education in high schools, and the Bureau has published a statistical summary in Bulletin, 1922, No. 14. The proportion of the number of schools giving some sort of instruction in matters pertaining to sex to the number of schools from which returns were obtained (about half of the total number of high schools in the country) is 41 per cent., varying between 17 per cent., in New Hampshire, and 100 per cent., in Utah. Sex education is classified as "emergency"—through lectures or occasional talks by members of the school staff or by physicians, nurses, State health officers, social workers, or ministers, sex hygiene exhibits, pamphlets, etc.—and "integrated," *i.e.* given incidentally in teaching the subjects of the regular curriculum. Although the former method is more frequently resorted to, a large majority of the principals, including those who at present provide no sex instruction, are in favour of the latter. So, evidently, are the authorities of the Public Health Service. These hold the view that "sex education should not be restricted to a certain body of information given at a special time and place, but rather should it be spread over a considerable time and given in various relations." They believe, in short, in breaking down the sex taboo. They point out, however, that few teachers have the combination of mental maturity, poise, sanity, sympathy, accurate knowledge of facts and ability to present them impersonally, and tact, which are requisite for beneficent sex education.

HIGHER education in the maritime provinces of eastern Canada suffers from excessive dispersion of its resources, there being six universities and a technical college doing work of university grade for a population barely exceeding one million. This is partly due to religious particularism. Last year the Carnegie Foundation for the Advancement of Teaching commissioned two experts—Dr. Learned of its own staff and President Sills of Bowdoin College—to visit this area and report on the educational situation with the view of suggesting a constructive policy, for the treatment particularly of the principal higher institutions, all of which had applied to the Foundation for aid. The visits were made in October and November 1921, and the Commissioners presented a report, which has been published as one of the Foundation's bulletins. The report concludes with a recommendation involving complete reconstruction, bringing together into a single university at Halifax, which would include as one of its colleges the Dalhousie University already located there, all the other five universities. It would, the commissioners remark, provide a real solution of the problem and would "prove particularly effective in handling a genuine honors curriculum . . . one of the precious features of English and Canadian universities that should constantly be held uppermost in planning new departures in higher education." The cost is estimated at 4½ million dollars. From an announcement in the *Times* of December 15 it would appear that the numerous difficulties in the way of realising the scheme have been surmounted, representatives of the corporations and governments concerned having arrived at agreement in regard to it.

Societies and Academies.

LONDON.

Linnean Society, December 14.—Dr. A. Smith Woodward, president, in the chair.—W. O. **Howarth**: On the occurrence of *Festuca rubra* in Britain. Representatives of three subspecies, three varieties, six subvarieties, and the forms of Hackel's *F. rubra*, occur in Britain.—H. W. **Pugsley**: British species of Calamintha and a species new to this country. The three recognised British species are said to be *Calamintha ascendens*, Jord., *C. Nepeta*, Savi, and *C. sylvatica*, Bromfield. The new form, first found near Swanage, in Dorset, in 1900, and again in 1912, was identified with *C. bætica*, Boiss. and Reut., although showing differences in minor features, which were attributed to climatic influence.—Lily **Batten**: The genus Polysiphonia; a critical revision of the British species, based upon anatomy. British species of Polysiphonia show great diversity of habitat. Four main types are distinguishable: (1) Ecorticate plant attached when young by rhizoids developed by longitudinal proliferation of basal siphons. Later, siphons of procumbent branches develop rhizoids, which may have discs at their distal ends, or may ramify among filamentous algæ, or may be swollen to form haustoria. (2) Species having a number of siphons or the beginning of cortication at the base, show elementary aggregation of the rhizoids to form one large disc. (3) Stunted procumbent branches develop at the base of the plant, which produce attachment rhizoids. (4) Corticate species having an upright habit develop a large disc-like expansion by the longitudinal proliferation of basal siphons and corticating cells. The genus is divided into thirteen ecorticate and eleven corticate species, and *P. spiralis* is described for the first time.

Aristotelian Society, December 18.—Prof. H. Wildon Carr in the chair.—Roy Wood **Sellars**: The double-knowledge approach to the mind-body problem. The motives which have worked for the exclusion of mind and consciousness from the brain appear upon examination to have been based upon hasty assumptions. We may call these the epistemological, the categorical, the methodological, and the theological methods. We must determine the reach and character of the knowledge gained by the science of external observation. This beginning is imperative. It seems that this knowledge consists of the critical deciphering by means of "scientific data" of the structure, order, composition, quantity, and behaviour of things and their parts. This is the kind of knowledge we have of bodies, but it is necessarily external. It cannot penetrate to the "filling" or content of being. But in our own case, our consciousness is just such a participation. A careful examination of the situation shows that changes in consciousness are indexes of operations which must also be attributed to the brain. Thus we know the brain in two ways. We should speak of it as the brain-mind. We must conceive the mind more substantialistically than we have done hitherto and make it mean a class of operations, and that which expresses itself in these operations. But we must also re-define consciousness. Leaving aside temporarily the structure of an adult consciousness let us define any element which we call the psychical. The psychical is not a stuff; that was the mistake of association psychology. It is merely a *quale*. Now a *quale* is not self-sufficient. It is a dimension of the content of being which can be given only by participation, not by external knowledge. It is indissolubly one with the responding brain-mind state. Its function is to guide the discharge of this state. Here we are partially on the inside of a high level of causality.

Royal Anthropological Institute, December 19.—Prof. J. L. Myres, vice-president, in the chair.—Cyril **Fox**: The distribution of population in the Cambridge region in early times, with special reference to the Bronze Age. The distribution in Britain of constructions attributable to the Neolithic and Early Bronze Ages suggests that the population was then limited to those areas, mainly upland, which must have been, under natural conditions, largely free from forest. A topographical analysis of finds and remains of all culture periods from the Neolithic to the Saxon in a limited area—the Cambridge region—was undertaken to determine whether this limitation was complete or partial, and when the clearing and occupation of forest areas commenced. The Cambridge region is very suitable for the inquiry, since it possesses a wide range of soils and has yielded numerous finds of all periods. The maps exhibited suggest (1) that the chalk belt and the eastern shoreline of the Fens were occupied from Neolithic times onwards; (2) that there was a gradual shift of population from N.E. to S.W., *i.e.* from the West Suffolk heathland to the fertile lands of the upper Cam and Ouse valleys, as agriculture developed; and (3) that the forest uplands were almost entirely unoccupied until the Roman period. The distribution of population in the Bronze Age is, generally speaking, of a character intermediate between that of the Age which preceded it and that which followed, but it presents features of special interest.

DUBLIN.

Royal Dublin Society, December 19.—Prof. J. A. Scott in the chair.—Six papers on the action of the oxides and the oxyacids of nitrogen on aromatic urethanes and ureas at low concentrations of the reacting substances.—(1) **H. Ryan** and **Anna Donnellan**: Diphenylurethane reacted with nitric acid much more slowly than diphenylnitrosamine. At the ordinary temperature it was slowly converted first into 4-nitrodiphenylurethane and afterwards into a mixture of 4·10-dinitro- and 2·10-dinitro-diphenylurethane. Concentrated nitric acid reacted with the urethane forming 2·4-8·10-tetranitrodiphenylurethane and finally sym. hexanitrodiphenylamine.—(2) **H. Ryan** and **N. Cullinane**: *o*-Tolyl-ethylurethane was oxidised by the oxides and the oxyacids of nitrogen yielding *o*-tolylurethane. The latter substance then underwent nitration, forming successively 4-nitro-2-methyl-phenylurethane and 4·6-dinitro-2-methylphenylurethane.—(3) **H. Ryan** and **Anna Connolly**: Ethylphenylurethane nitrated at the ordinary temperature gives 4-nitro- and 2·4-dinitrophenylurethane. In hot solutions, on the other hand, the urethane, like *o*-tolyl-ethylurethane, underwent oxidation in addition to nitration. In the latter case the products isolated were 2·4-dinitro- and 2·4-6-trinitro-phenylurethane.—(4) **H. Ryan** and **J. O'Donovan**: Phenylbenzylurethane was converted by nitrogen peroxide into 4-nitrophenylbenzylurethane and a trinitrophenylbenzylurethane melting at 110° C. Similar results were obtained by the action of nitric acid at low temperatures on the urethane. At more or less high temperatures and concentrations of the substances a tetranitrophenylbenzylurethane melting at 126° C., a pentanitro derivative melting at 274° C. together with 4-nitrobenzoic acid, 2·4-dinitro-phenylurethane and pentanitrophenylbenzylamine.—(5) **H. Ryan** and **P. O'Toole**: Phenylurea and as-diphenyl-

urea reacted easily with oxides of nitrogen, the former giving nitro-phenols and the latter diphenylamine derivatives; *s*-diphenylurea and triphenylurea under the same conditions gave a dinitro-diphenylurea and a trinitrotriphenylurea respectively. Nitrous acid converted phenylurea and *s*-diphenylurea into their nitroso derivatives. Nitric acid converted phenylurea into phenylurea nitrate, *p*-nitrophenylurea, and 2·4-dinitro-phenylnitrourea. With *s*-diphenylurea it gave mono-, di- and tetranitro derivatives, and with triphenylurea it formed di-, tri- and pentanitro derivatives.—(6) **H. Ryan and M. Sweeney**: Phenylmethylurea and nitric acid underwent no change in the absence of nitrous acid. In the presence of the latter acid it was converted into methylaniline, phenylmethylnitrosamine, and then successively into 2- and 4-nitrophenylmethylnitrosamine, 2·4-dinitro- and 2·4·6-trinitro-phenyl-methylamine. With concentrated nitric acid, tetryl was formed readily and in a pure condition from the urea.

Diary of Societies.

SATURDAY, JANUARY 13.

GILBERT WHITE FELLOWSHIP, at 2.15.—Visit to the Geological Museum, Jermyn Street.

NATIONAL UNION OF SCIENTIFIC WORKERS (Annual Council Meeting) (at Caxton Hall), at 2.30.

MONDAY, JANUARY 15.

CHEMICAL INDUSTRY CLUB (2 Whitehall Court), at 8.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Lt.-Col. D. Cree: The Yugo-Slavia–Hungarian Boundary.

TUESDAY, JANUARY 16.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. F. G. Donnan: Semi-permeable Membranes and Colloid Chemistry (1). The Theory of Ionic Equilibria and Semi-permeable Membranes.

ROYAL SOCIETY OF MEDICINE, at 5.—General Meeting.

ROYAL STATISTICAL SOCIETY (at Royal Society of Arts), at 5.15.—Dr. R. Dudfield and others: Discussion on The Registration of Disease.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—J. C. Dollman: Address.

ILLUMINATING ENGINEERING SOCIETY (at Royal Society of Arts), at , 8.—C. E. Greenslade, J. E. S. White and others: Discussion on the Need for Suitable Training in Illuminating Engineering.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—F. W. H. Migeod: The Bedde Group of Tribes of N. Nigeria.

ROYAL SOCIETY OF MEDICINE (Pathology Section), at 8.30.—Prof. M. J. Stewart and Dr. J. le F. C. Burrow: Malignant Spheno-occipital Chordoma.—Dr. A. J. Eagleton and Miss E. M. Baxter: The Serological Classification of Virulent B. Diphtheriæ.—Dr. C. C. Okell and Miss E. M. Baxter: The Fermentative Reactions of Virulent B. Diphtheriæ.

WEDNESDAY, JANUARY 17.

ROYAL SOCIETY OF MEDICINE (History of Medicine Section), at 5.—W. H. S. Jones: Medical Etiquette in Ancient Times.—Dr. C. Singer: The Hippocratic Oath.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—Dr. C. Chree: Aurora and Allied Problems (Presidential Address).

ROYAL SOCIETY OF ARTS, at 8.—C. A. Klein: Hygienic Methods in Painting: the Damp Rubbing-down Process.

ENTOMOLOGICAL SOCIETY OF LONDON, at 8.—(Annual Meeting).

ROYAL MICROSCOPICAL SOCIETY (Annual Meeting), at 8.—Prof. F. J. Cheshire: The Petrological Microscope and its Optical Evolution (Presidential Address).

THURSDAY, JANUARY 18.

ROYAL SOCIETY, at 4.30.—*Probable Papers.*—J. Barcroft: Observations on the Effect of High Altitude on the Physiological Processes of the Human Body.—Prof. E. W. MacBride: Some New Light on the Inheritance of Acquired Characters.—C. F. Cooper: *Baluchitherium osborni* (? syn. *Indricotherium turgaicum*. Borrissyak).—J. A. Gunn and K. J. Franklin: The Sympathetic Innervation of the Vagina.—H. G. Cannon: The Metabolic Gradient of the Frog's Egg.—Basiswar Sen: The Relation between Permeability Variation and Plant Movements.—Dr. H. L. Duke: An Inquiry into an Outbreak of Human Trypanosomiasis in a *Morsitans* Belt to the East of Mwanza, Tanganyika Territory.—Dr. L. Dollo: Le Centenaire des Iguanodons (1822–1922).

LINNEAN SOCIETY OF LONDON, at 5.—Capt. G. H. Wilkins: An Account of the Shackleton-Rowlett Expedition in the *Quest* to the Antarctic Regions.—Miss Helena Bandulska: The Cuticular Structure of certain Dicotyledonous and Coniferous Leaves from the Middle Eocene Flora and Bournemouth.—W. R. Sherrin: A Pocket Herbarium of the British Mosses.

LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5.—L. J. Mordell: Lecture on An Introductory Account of the Arithmetical Theory of Algebraic Numbers, and its recent Developments.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 5.30.—Major J. D. Rennie: Flying Boats.

INSTITUTION OF MINING AND METALLURGY (at Geological Society), at 5.30.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—G. H. Nelson: Works Production.

CHEMICAL SOCIETY, at 8.

ROYAL SOCIETY OF MEDICINE (Dermatology Section), at 8.30.—Dr. J. W. McNee and Dr. A. M. H. Gray: A Chemical and Histological Study of a Case of Sclerema neonatorum.—J. E. A. McDonah: The Use of Manganese as a Chemo-therapeutic Preparation

FRIDAY, JANUARY 19.

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.—The Earl of Ronaldshay: A Clash of Ideals as a Cause of Indian Unrest.

ROYAL SOCIETY OF MEDICINE (Otology Section), at 5.—Dr. L. Turner and J. S. Fraser: Demonstration of Labyrinthitis as a complication of Middle Ear Suppuration.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—L. Pendred: The Problems of the Engine Indicator.—Prof. F. W. Burstall: A New Form of Optical Indicator.—W. G. Collins: Micro-indicator for High-speed Engines.—H. Wood: R.A.E. Electrical Indicator for High-speed Internal-Combustion Engines, and Gauge for Maximum Pressures.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—S. C. Saunders: Paraffin as Fuel for Marine Motors.—T. H. Sanders: Laminated Springs.

ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section), at 8.30.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Sir James Dewar: Soap Films as Detectors: Stream Lines; Vortex Motion, and Sound.

SATURDAY, JANUARY 20.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Walford Davies: Speech Rhythm in Vocal Music (1).

PUBLIC LECTURES.

THURSDAY, JANUARY 18.

LONDON HOSPITAL MEDICAL COLLEGE, at 4.30.—W. A. M. Smart: The Mathematical Basis of Physiological Problems. (Succeeding Lectures on January 25, February 1, 8, 15, 22, and March 1 and 8.)

UNIVERSITY COLLEGE, at 5.30.—J. C. Flügel: The Psychology of Folklore.

KING'S COLLEGE, at 5.30.—Prof. W. Barthold: The Nomads of Central Asia. (Succeeding Lectures on January 25, February 1, 8, 15, and 22.)

SATURDAY, JANUARY 20.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss M. A. Murray: Ancient Egypt and the Aegean Islands.

UNIVERSITY OF LONDON.

NOTICE IS HEREBY GIVEN that the Senate will proceed to elect EXTERNAL EXAMINERS for the Examinations above Matriculation as follows. Except when otherwise stated, Examiners will act in all Examinations in which the subject is included. Where Examiners are to be appointed for (*a*) Intermediate Examinations only and (*b*) Final and Higher Examinations only, the fact is indicated after the name of the subject below: in these cases the same Examiner cannot hold both appointments.

FOR THE SESSION 1923-24.

EXAMINATIONS OTHER THAN MEDICAL.

Anatomy.
Botany (Final and Higher, two; Intermediate, two).
British Constitution.
Chemistry (Final and Higher, one; Intermediate, two).
Common Law.
Economics (Final one; Intermediate, two).
Education.
English Constitutional Law (two).
English (Final, one).
Equity.
French (Final, one; Intermediate, two).
Geography.
Geology.
German.
Greek (Final, one; Intermediate, two).
Hindu Law.
History (Final, one).
History and Principles of Taxation and Tithes.
Indian Evidence Act.
Jurisprudence and History of Roman Law.
Latin (Intermediate, two).
Mahommedan Law.
Mathematics (Final, one; Intermediate, four).
Music.
Philosophy (two).
Physics (Final, two; Intermediate, one).
Physiology.
Public Administration and Finance.
Sociology.
Veterinary Physiology.

FOR THE SECOND EXAMINATION FOR MEDICAL DEGREES FOR THE SESSION 1923-24.

Anatomy (two). Physiology.

HIGHER EXAMINATIONS FOR MEDICAL DEGREES FOR THE SESSION 1923-24.

Bacteriology. Forensic Medicine and Hygiene (two). Pathology. State Medicine.

N.B.—Attention is drawn to the provision of Statute 124, whereby the Senate is required, if practicable, to appoint at least one Examiner who is not a Teacher of the University.

Application Form (or Forms if more than one Examinership is applied for) and particulars of the remuneration and duties can be obtained from the EXTERNAL REGISTRAR.

Candidates must send in their names to the External Registrar, GEO. F. GOODCHILD, M.A., B.Sc., with any attestation of their qualifications they may think desirable, on or before Monday, January 29, 1923, in respect of Examinerships other than Medical subjects; and on or before Saturday, February 10, 1923, in respect of Medical Examinerships. (Envelopes should be marked "Examinership.")

The Senate desire that no application of any kind be made to individual members.

If testimonials are submitted, one copy only of each is required. In no case should original testimonials be submitted. If more than one Examinership is applied for, a separate application, complete with copy of testimonial, must be forwarded in respect of each Examinership. The appointments in Engineering will be made by the Senate towards the end of February; those in Medicine towards the end of May; and the remainder towards the end of March. Applicants who desire that the result should be communicated to them are requested to enclose a stamped and addressed envelope with their applications.

E. G. PERRY, Principal Officer.

University of London,
South Kensington, S.W.7,
January 1923.

UNIVERSITY OF LONDON.

A Course of ten Lectures on "THE MICRO-ORGANIC POPULATION OF THE SOIL" will be given by SIR JOHN RUSSELL, F.R.S. (Director) and STAFF OF THE ROTHAMSTED EXPERIMENTAL STATION in the Lecture Theatre of the Botanical Department at UNIVERSITY COLLEGE, LONDON (Gower Street, W.C.1), on FEBRUARY 5, 7, 12, 14, 19, 21, and 27, and MARCH 1, 5, and 7, 1923, at 5 P.M. At the first Lecture, the Chair will be taken by Professor J. B. FARMER, F.R.S. ADMISSION FREE, WITHOUT TICKET. A Syllabus of the Lectures is obtainable on application to the undersigned.

EDWIN DELLER, Academic Registrar.

UNIVERSITY OF LONDON.

A Course of eight Lectures in Physiology on "THE PHYSIOLOGY OF THE CORTEX AS INVESTIGATED BY THE METHOD OF CONDITIONED REFLEXES," will be given by DR. G. ANREP, M.D., at UNIVERSITY COLLEGE, LONDON (Gower Street, W.C.1), on FRIDAYS, January 26, February 2, 9, 16, 23, and March 2, 9, and 16, at 5 P.M. ADMISSION FREE, WITHOUT TICKET. Syllabus obtainable on application to the undersigned.

EDWIN DELLER, Academic Registrar.

LEICESTER MUSEUM.

ASSISTANT required with knowledge of Palæontology and Invertebrate Zoology. Museum experience desirable. Commencing salary £250 per annum. Applications accompanied by copies of three recent testimonials to be delivered on or before February 25, addressed to the DIRECTOR, The Museum, New Walk, Leicester.

CHELSEA POLYTECHNIC,

CHELSEA, S.W.3.

Day and Evening Courses in Science under Recognised Teachers of London University.

I. **INDUSTRIAL CHEMISTRY DEPARTMENT.** Technical Courses in Analytical and Manufacturing Chemistry, Pharmacy, Food and Drugs, A.I.C. Courses, Metallurgy, Assaying, Foundry Work, Research.

II. **INDUSTRIAL PHYSICS DEPARTMENT.** Practical work in General Physics, Applications to Industries, Metrology, Calorimetry, Illumination, Acoustics, Electrical Measurement, Research.

III. **BIOLOGICAL AND GEOLOGICAL DEPARTMENT.** Courses for B.Sc., etc., in Botany, Geology, Mineralogy, Zoology, Special Courses in Bio-chemistry, Bio-physics, Bacteriology, Physiology, Hygiene, Entomology, Plant Pathology. Course for Tropical Planters, Research.

Lent Term began on January 9, 1923.

SIDNEY SKINNER, M.A.
Principal.

Telephone: Kensington 809.

ROYAL INSTITUTION OF GREAT BRITAIN,

21 ALBEMARLE STREET, W.1.

GENERAL COURSES OF LECTURES BEFORE EASTER 1923.

AT THREE O'CLOCK AFTERNOON.

Professor F. G. DONNAN, F.R.S. Two Lectures on "Semi-Permeable Membranes and Colloid Chemistry." On Tuesdays, January 16, 23.

Mr. R. D. OLDHAM, F.R.S. Two Lectures on "The Character and Cause of Earthquakes." On Tuesdays, January 30, February 6.

Professor A. C. PEARSON, Two Lectures on "Greek Civilization and To-day." On Tuesday, February 13, Wednesday, February 21.

Sir ARTHUR SHIPLEY, F.R.S. Two Lectures on "Life and its Rhythms." On Tuesdays, February 27, March 6.

Professor CHARLES G. SELIGMAN, F.R.S. Two Lectures on "Rain-makers and Divine Kings of the Nile Valley." On Tuesdays, March 13, 20.

The Hon. JOHN W. FORTESCUE. Two Lectures on 1. "The British Soldier and the Regimental Officer at the Close of the Napoleonic War," 2. "The Campaigns of the British Army, 1815-1838." On Thursdays, January 18, 25.

Professor H. M. HEILBRON, F.C.S. Two Lectures on "The Photo-synthesis of Plant Products." On Thursdays, February 1, 8.

Professor B. MELVILL JONES. Two Lectures on "Recent Experiments in Aerial Surveying." On Thursdays, February 15, 22.

Mr. THEODORE STEVENS. Two Lectures on "Water Power of the Empire." On Thursdays, March 1, 8.

Lieut.-Colonel E. F. STRANGE, C.B.E. Two Lectures on "Japanese and Chinese Lacquer." On Thursdays, March 15, 22.

Sir WALFORD DAVIES. Two Lectures on "Speech Rhythm in Vocal Music." On Saturdays, January 20, 27.

Mr. J. C. SQUIRE. Two Lectures on "Subject in Poetry." On Saturdays, February 3, 10.

Sir ERNEST RUTHERFORD, F.R.S., Prof. of Natural Philosophy. Six Lectures on "Atomic Projectiles and their Properties." On Saturdays, February 17, 24, March 3, 10, 17, 24.

Subscription (Non-Members) to all Courses of Lectures (excepting the Friday Evening Discourses and the Juvenile Lectures), Four Guineas.

Subscription to a Single Course, Two Guineas or One Guinea.

The Friday meetings will begin on January 19, at 9 P.M., when Professor Sir JAMES DEWAR will give a Discourse on "Soap Films as Detectors of Stream Lines; Vortex Motion; and Sound." Succeeding Discourses will probably be given by Sir ALMROTH WRIGHT, Sir JOHN RUSSELL, Sir ERNEST RUTHERFORD, Professors A. V. HILL, A. S. EDDINGTON, Mr. C. F. CROSS, Mr. G. C. SIMPSON, Dr. M. R. JAMES, and other gentlemen.

Information as to Membership and other matters connected with the Institution can be had at the Secretarial Office, No. 21 Albemarle St., W.1.

BATTERSEA POLYTECHNIC,

LONDON, S.W.11.

Principal—ROBERT H. PICKARD, D.Sc., F.R.S.

Head of Chemical Department—J. KENYON, D.Sc., F.I.C.

Day and Evening Courses in Pure Chemistry (Inorganic and Organic) in preparation for University Degrees and A.I.C. and other professional examinations.

Special Technological Courses in Chemical Engineering, Oils, Fats and Waxes, Mineral Oils and Waxes, Toilet Soaps Manufacture, Lubricating Oils and Greases, Paper Making and Paper Testing, Paper Making (Engineering), Commercial Paper Work, Applied Bacteriology, Testing of Disinfectants, Analysis of Foods, Waters, Fertilisers and Feeding Stuffs, Microscopy of Food and Drugs, Flour Milling, etc.

The instruction is both theoretical and practical, fully equipped laboratories being provided.

NO. 2777, VOL. 111]

Edward Jenner.

ON January 26, 1823, Dr. Edward Jenner, the discoverer of protective vaccination against smallpox, died in his home at Berkeley—a village of Gloucestershire—where he had lived long and practised as a country doctor. For centuries before, smallpox had been a terrible scourge in all countries and vast numbers of people had been swept away in every generation. Based on the observation that one attack of the disease confers, on those who recover, a lifelong immunity, an attempt had been made to imitate the natural disease by artificial inoculation of smallpox, in the hope that the artificially-produced disease might be mild, while creating at the same time a lasting immunity. In England this ancient process of inoculation, or as it was called variolisation, was introduced from Turkey early in the eighteenth century through the instrumentality of Lady Mary Wortley Montagu (1689–1762) and rapidly became widely disseminated. Its disadvantages were twofold. In the first place, it was impossible to gauge how severe would be the effects of the inoculation, which in many cases were severe or even fatal; and in the second place, the disease produced was smallpox which, like the natural disease, was highly contagious, and although the inoculated person might survive and become immune he might disseminate the disease to others.

Jenner's discovery entirely removed these difficulties. Following up the country tradition that milkers who contract cowpox on their hands from infected animals are not capable of contracting smallpox, Jenner made experiments in which matter was taken from infected persons or directly from the cow itself, and he inoculated this into human beings, who developed what is called vaccinia. That these persons become immune to smallpox was shown by Jenner, who subsequently variolated them without being able to induce smallpox. More remarkable still, he showed that vaccinia can be transmitted from person to person in series without losing its properties. Jennerian vaccination is in its essence different from smallpox inoculation as previously practised, for the disease produced is mild and is not contagious.

Jenner's first experiments were made in 1796, and his famous "Inquiry into the Causes and Effects of the Variolae vaccinae" was published in 1798. The process of vaccination was instantly recognised as a great advance and rapidly attained a world-wide dissemination, largely through Jenner's own untiring efforts. A century has established the fact that Jenner's wonderful discovery must rank among the most beneficent known in the history of mankind, and

although he has had and still has detractors, the vast mass of opinion of those most entitled to form a judgment of its merits would be in agreement with that of the learned August Hirsch, that "it can only be folly or stupidity that would seek nowadays to minimise or to question the immortal merits of Jenner."

When Jenner died Louis Pasteur was a month-old babe. Thus two great lives were linked: one immortal for a single great empirical discovery, the other destined to carry on the torch and found a science. It is doubtful if even yet the precise relationships of smallpox to cowpox are fully understood, in spite of the great mass of experimental work devoted to the problem during the past hundred years, nor can we point to any great advance in knowledge of the exact nature of the viruses concerned. Opinion, however, has quite definitely crystallised on one point, namely, that cowpox—now a great rarity in nature—is no spontaneous disease of the cow but is simply the bovine response to accidental infection with smallpox virus or vaccinia, conveyed by the hand of the milker. The evidence on which this statement is based rests fairly securely (1) on the successful results of experimental transference of variola to the cow, (2) the benign nature of the resultant lesions, and (3) the undoubted immunity to smallpox which the bovine disease confers when retransferred to man. It is true that, in the past century, schools of dualists and unicists have engaged in acrimonious discussion, but the spoils of the battle rest with the latter. Cowpox or vaccinia is simply an attenuated form of smallpox, and were there no smallpox there would be no naturally occurring cowpox. Further, with none of the other eruptive lesions in the domestic animals (horse-pox, sheep-pox, etc.) can smallpox be brought into similar relationship. These others are independent infections.

The diversity of response to one and the same virus by various animal species has been a fruitful field of speculation since Pasteur's time, and we know that Pasteur's chief concern was to expand Jenner's discovery so as to secure, for immunisation purposes, some strain of other living viruses, which, with the property of virulence removed or at least depressed, would yet adequately perform the function of immunising against the fully virulent variety. In swine erysipelas, Pasteur claimed to have secured the desired attenuation by passage through another species—a result on all fours with Jenner's observation as we now understand and interpret it. These normal immunities and explanations of them will doubtless for long be the subject of research, and in the present issue we take the opportunity of reprinting the main part of a recent address by Prof. J. C. G. Ledingham, who discusses the present state of knowledge in relation to normal immunity of species to various infections, and the factors on which such immunities have been alleged to depend.

Science in Secondary Schools.

THE committees appointed to consider the position of Natural Science, Modern Languages, Classics, and English in the educational system of Great Britain have now formulated their reports, and the Board of Education has issued a circular (No. 1294, December 6, 1922) in which some of the consequences of these reports are discussed. One of these is the question of the amount of time to be given to the teaching of individual subjects, and as the result a time-table has been provisionally drawn up which provides for 35 to 37 teaching periods of 45 minutes each per week in school, and not including time necessary for exercises and preparation. The Science Committee considers that not less than six periods per week should be given to that subject. This means about three-quarters of an hour per day, and no science teacher will be disposed to consider that too much for boys between the ages of 13 and 16.

The main point for consideration relates to the subjects which should be taught in the course of the school life, say altogether eight or nine years. As usually arranged, the course begins with nature study, followed by physics and chemistry, and no time is provided for subjects like astronomy and the elements of geology, which are necessary for the apprehension of common terrestrial phenomena. In considering such a question, regard should be had to the objects to be kept in view in teaching natural science at school. The first consideration should not be the usefulness of the applications of science, but its purpose should be to furnish the mind and supply some kind of clue to the phenomena of the physical world into which man is introduced at birth.

It is further necessary to cultivate habits of attentive observation and careful reasoning, so that some at least of the delusions to which all are exposed should be less deadly. It is, however, not necessary or desirable that all the subjects referred to should be taught at the same time, and they need not be taught with the same degree of thoroughness. Much general information may be imparted in a well-chosen series of lessons in nature study, while chemistry and physics, begun later, should be carried on to the end of school days. Many illustrations of facts relating to other subjects may be introduced in a less formal manner, not as school lessons but with the aid of the lantern and a sort of popular lecture, not to be followed by any examination or other test which only frightens young people away.

The circular from the Board of Education contains the remark that with "four periods of 45 minutes in the

morning and three in the afternoon for five days per week, a full week consists of thirty-five periods." But it will be found that these thirty-five periods for instruction include two for physical exercises, two for manual work, two for drawing, and one for music, or seven periods altogether, and some of these may be interrupted or replaced temporarily without loss. Thus when games are properly organised they may replace physical exercises, and manual work may, to some extent, be replaced by experimental work in the physical or chemical laboratory at the suitable age. These are questions which will not be settled immediately, and with others they might well be considered at a meeting of the Science Masters' Association, especially with reference to the question as to how many of the science periods should be given to physical and how many to biological studies, the latter being often totally neglected.

Archæology and Technology of Carpets.

Hand-woven Carpets: Oriental and European. By A. F. Kendrick and C. E. C. Tattersall. Vol. 1. Pp. xi+198. Vol. 2. Pp. xi+205 plates. (Benn Bros., Ltd., 1922.) 105*s.* net.

THE pile carpet, though now an essential element in European domestic economy, is of foreign origin. Weaving is one of the most ancient and widespread of arts, and to produce a pattern by interlacing continuous threads is a natural development from it. From this to using threads of different colours is an easy transition. But to set the threads in a vast number of short lengths upon end, and to pack them so tight that they keep that position, entails so much skill and uses so much material that they can only have been originally produced in response to very special conditions.

Those conditions are encountered in the life of the nomads of Central Asia. The extreme changes of temperature in that part of the world, the demand of the nomadic life for portable and non-conducting fabrics, and the ample supply of wool available to these herdsmen, fit in with the archæological findings. Central Asia is thus designated as the home of the pile carpet. Recent excavations in that region have brought to light small fragments of such ancient carpets. Most curiously, however, the earliest complete pile carpet known is of European manufacture. It was prepared toward the end of the twelfth century in a nunnery at Quedlinburg in the Harz Mountains, and represents the well-known medieval theme of the "Marriage of Mercury and Philology." Oriental literary influence was very strong in Europe at that period. The art of carpet-weaving may well have come to Europe at this time along with "Arabian" science.

The earliest carpet of which a detailed description has come down to us, was made for the Persian Chosroes (531–579), and his successors used it until the last Sassanian king, Jazdegerd (632–651), pursued by the Arabs, was assassinated at Merv. The Persians are said to have had two loves, gardens and drinking, and this carpet was used for the drinking feasts in the stormy winter season when it was impossible to stay in the garden. The carpet was designed to portray a garden and was called "The Spring of Chosroes." It was woven as though planted with trees and spring flowers, intersected by brooks and pathways. Several very ancient Persian carpets, with a design which recalls that of Chosroes, have survived.

India was much later in the field than Persia, and does not appear to have produced pile carpets until the sixteenth century. Pile carpets were devised to meet the needs of colder climates than India, and in such climates suitable wool for making them can more easily be grown. The export trade in Indian carpets began in the seventeenth century, and has now reached very considerable proportions. After the middle of the nineteenth century carpet-knotting was begun in the jails, and many of these "jail-carpets" are now on the market. They are mostly copied from old patterns.

In Turkey the carpet industry was stimulated in the early part of the sixteenth century, when Selim I. in 1514, and again Suleiman I. in 1534 entered Tabriz and carried off craftsmen to Asia Minor. Much earlier, however, an export trade between the Anatolian ports and Europe—especially Venice—had been opened up and carpets began to come westward. Few of these have survived, but a number are represented in the works of Dutch and Italian artists, Jan van Eyck, Memlinc, Van der Goes, Holbein, Ghirlandajo, Pinturicchio, and others.

The first European country to develop a carpet industry was Spain, which was producing carpets of similar design to the Turkish in the fifteenth century. In England little was known of carpets until at least a century later. Paul Hentzer, a German who came to London in 1598, states that Queen Elizabeth's presence-chamber at Greenwich was strewn with hay. Even rush-matting, though used by the French from the beginning of the fifteenth century, does not seem to have come into general use in this country till the reign of James I. Pile carpets, however, were beginning to be imported into England from the East about the middle of the sixteenth century, and the actual making of them here was not long delayed. A carpet represented on a fine plate in this volume has in the middle the arms of England with the initials of Queen Elizabeth and the date 1570.

Before the end of Elizabeth's reign the English

Turkey Company had begun direct trading with the Eastern Mediterranean, and carpets were more easily obtained. Some of these were copied more or less faithfully in England. A "Turkey" carpet of English manufacture is in the Victoria and Albert Museum bearing the inscription, "Feare God and keepe his commandements made in the yeare 1603." Some light is thrown on the manufacture of such carpets by a chapter in Hakluyt's "Voyages": "Certaine directions . . . to M. Morgan Hubblethorne, Dier, sent into Persia 1579," where we read: "In Persia you shall finde carpets of coarse thrummed wool, the best of the world, and excellently coloured: those cities and towns you must repair to, and you must use means to learn all the order of the dying of those thrums, which are so dyed as neither rain, wine, nor yet vinegar can stain. . . . If before you return you could procure a singular good workman in the art of Turkish carpet-making you should bring the art into this realm."

These magnificently illustrated volumes provide a complete key not only to the history of carpetry, but also to the technology and identification of carpets both ancient and modern. The text is lucidly and attractively written. The illustrations are largely drawn from the collection at the Victoria and Albert Museum, to which have been added many of the plates from Neugebauer and Orandi's "Handbuch der orientalischen Teppichkunde" and other sources. The authors, printers, and publishers are to be congratulated heartily on this singularly attractive production.

CHARLES SINGER.

Vitalism and Anti-Vitalism.

Grundlagen einer Biodynamik. von Prof. Dr. Johannes Reinke. (Abhandlungen zur theoretischen Biologie. Herausgegeben von Prof. Dr. Julius Schaxel, Heft 16.) Pp. v+160. (Berlin: Gebrüder Borntraeger, 1922.) 12*s*.

Handbuch der Pflanzenanatomie. Herausgegeben von Prof. K. Linsbauer. 1 Abteilung, 1 Teil: Cytologie. Band 1: Zelle und Cytoplasma. Von Henrik Lundegårdh. Pp. xii+193-402. (Berlin: Gebrüder Borntraeger, 1922.) 24*s*.

L'Organisation de la matière dans ses rapports avec la vie: études d'anatomie générale et de morphologie expérimentale sur le tissu conjonctif et le nerf. Par Prof. Jean Nageotte. Pp. vi+560+4 planches. (Paris: Félix Alcan, 1922.) 50 francs.

THESE three books all deal with the fundamental question of the relation of the activities denoted by the term "life" to the constitution of the matter in which they are exhibited. When living matter is analysed (and necessarily killed in the process) it is found to consist of proteids, fats, carbohydrates together with certain metallic salts. What has made this mixture "alive"? Is there, as Verworn supposed, a living substance *par excellence* for which the other materials in protoplasm constitute an environment? Verworn named his hypothetical substance "biogen," and "life" was supposed to consist of the characteristic reactions of this substance with surrounding materials; reactions by which the biogen molecule was partially destroyed, but as the result of which a residue was left from which a new biogen molecule was reconstituted, and so the continuity of life was maintained. If, on the other hand, the difficulties involved in the supposition of a specific biogen molecule are too great to be overcome, life may be supposed to consist in the mutual reactions of a characteristic mixture of substances, and no single substance viewed apart from the others can be considered alive. In this case all depends on the specificity of the mixture—in a word, *on the physical structure of the living matter*. We may phrase it in another way if we say that life depends on the *juxtaposition in a definite way of unlike substances*. But how is this physical structure maintained? Is there a reduced copy of the frog in the frog's egg? That no typical physical structure will explain living phenomena has been clearly proved by Driesch. No imaginable "constellation of parts" would survive the changes described by Driesch in his account of his experiments and yet yield the same typical result which was given by the original mixture.

Now the authors of the three books before us all agree in rejecting the biogen theory: the first falls back with some hesitation and the use of different words on an explanation which is closely akin to the entelechy of Driesch, the second ignores the difficulties raised by the view that protoplasm is a mixture, but Prof. Nageotte vehemently denounces vitalism. The only reason, he asserts, that we believe in such an empty concept is the unfortunate circumstance that we ourselves are alive, and our life is the "accidental" result of our organisation—a phrase which "gives us furiously to think." It is not quite clear how on Prof. Nageotte's view science itself can exist, and how an "accidental result of our organisation" can either acquire or impart "knowledge" of phenomena outside us. But as we shall see, Prof. Nageotte, while like Balaam he begins with the intention of cursing vitalism, is led like the prophet to bless it altogether—although he is not conscious of the fact.

Prof. Reinke's book is an attempt to make a comprehensive survey of the characteristic peculiarities of animals and plants and so to deduce general laws

governing life. The laws which he formulates are three in number, namely, (1) All life begins from pre-existing life; (2) There is a tendency to the restitution and maintenance of typical form in spite of its continual destruction by catabolism; (3) Psychic phenomena are only manifested in connexion with living material. But, according to Reinke, it is by no means allowable to attribute a "psyche" to all forms of living matter; it is a contradiction in words to imagine a "psyche" where there is no evidence of sensation; and so he is unable to attribute feeling to plants. Since, however, the protoplasm of plants obeys the same laws as that of animals, and its activities are not explicable on any conceivable theory of physical structure, he invents the word "diaphysical" to denote the basis of these activities. (It is a pity that he seems to be unacquainted with the work of Sir Bahadur Bose.) "The peculiar combination of 'elementary mechanisms' in the organism constitutes its being and is of diaphysical nature." He pours scorn, which we think is deserved, on "materialistic vitalism." By this phrase is meant the attempt to escape from the impasse created by the impossibility of explaining life by physical structure, through the invention of an imaginary series of units many thousands of times smaller than the electron, to which are attributed imaginary properties so as to account for living phenomena. He states, "By assimilation as by other chemical processes (cf. the formation of chlorophyll and enzyme) we only obtain lifeless substances. The 'vitalising' of these substances takes place only by their insertion in the framework of protoplasm"—and this essentially vital step he terms "epiplasty."

As might be expected, Prof. Reinke encounters the Mendelian "gene" and in our opinion takes it far too seriously. A gene he considers to be a vital unit "which controls energy, material, and pattern; out of which definite form develops." It is becoming every day clearer *that a "gene" is not a definite unit of structure at all, but simply the measure of the amount of pathological damage which the hereditary substance has undergone*. It is a measure, in a word, of the "imperfection of regulation." The differences between two allied natural races are not measurable in genes but in different adaptations; the overwhelming majority of Mendelian mutations arise under the unhealthy circumstances of domestication: they are nearly all recessive to the parent strain, from which they differ not only in special diagnostic marks but in weaker constitutions; in the few cases where they are dominant to the normal form they are generally so virulently pathological that when crossed with their like the results are lethal.

It seems to us after careful perusal that all that Prof. Reinke states as to the peculiarity of living processes has been said many times before. Reinke's influence of "the whole on the parts," and his "dominants" are simply Driesch's entelechy in other language—while so long ago as the early 'eighties Tyndall stated that it was not the nature of the forces manifested in living matter but their combination which constituted the miracle of life. The importance of the book consists in the tardy recognition, by a leading botanist, of the impossibility of explaining life by physics and chemistry alone.

Prof. Lundegårdh's "Zelle und Cytoplasma" is one of a series of text-books devoted to the elucidation of the anatomy of plants, and consequently it is concerned almost exclusively with the cytology of vegetable cells.

It is beautifully illustrated, and so far as plants are concerned the information contained in it is well up-to-date; but the author seems to be less well informed on the most recent advances in animal cytology. It is a characteristic botanical point of view to attempt to deny, as he does, the all-importance of the nucleus in the transmission of hereditary qualities. According to him the nucleus derives its importance only from containing in it some links in the chain of chemical reactions which make up metabolism. Nature's critical experiment in the formation of the animal spermatozoon is ignored by him. When we find that in animals the sole contribution of the father which contains the basis of all his hereditarily transmissible qualities is a condensed nucleus, the question as to the function of the nucleus seems to be decisively answered.

Lundegårdh agrees with Reinke in considering protoplasm to be a mixture of various colloids of different chemical composition. He emphasises the enormous variety of chemical changes which such a constitution would entail, and with the perpetual change from sol to gel and *vice versa*; he shows that the visible structure must be continually altering and that the granular theory of the constitution of protoplasm propounded by Altmann, the filar theory of Flemming, and the foam-work theory of Bütschli, may all be to a certain extent true under certain conditions, but that under other conditions there may be no visible structure at all, and that the living material may present the appearance of a homogeneous fluid. He, like Reinke, will have nothing to do with a hypothetical ultramicroscopical constitution of invisible units as an explanation of life. He condemns with equal severity the supposed difference between "idioplasm" and "somatoplasm," and he sharply criticises the unthinking acceptance of what can be seen in preserved specimens as a true indication of what exists during life. It is here that his arguments would be very much reinforced by a better acquaintance with the results obtained by Chambers

and Seifert in the microdissection of living cells. The attempt to constitute the mysterious mitochondria into permanent cell-organs is equally opposed; he asserts that they are secondary formations, and that in the growing point of Anthoceros the youngest cells are devoid of them but that they appear in the older cells.

The great defect of Lundegårdh's exposition seems to us to be his failure to show how a mixture of substances with their consequent reactions can be an explanation of the typical character and persistence of living phenomena. When a mixture of substances is enclosed in a test-tube definite reactions are set up which progress towards a state of eventual equilibrium, and an end-state is reached with a mixture of different substances and in different proportions from that with which we started. In protoplasm, on the contrary, the typical nature and proportions of the mixture must somehow be maintained even in spite of increase in quantity—and these facts cannot be explained by any purely physical and chemical analysis.

Prof. Nageotte's book is widely different from the other two. Although it professedly deals with the relation of matter to life, it really consists of the record of a series of fascinating experiments on animal grafts. The results obtained are new and startling, but they are illustrated by what can only be termed an extremely bad series of figures. These are prints from photographs, hazy and very insufficiently lettered, and we can only deplore that such good work should be misrepresented by such feeble illustrations.

We have said that Nageotte begins by condemning vitalism. He states that the essential peculiarity of living things is not their chemical constitution, but a certain order in what he terms the micellar structure, the micellæ being supra-molecular complexes. Agreed; but it is precisely the genesis and maintenance of this order which is the inexplicable fact in living things. Nageotte even tries to prove that there is a transition between dead proteid and living protoplasm, and as the principal support of his anti-vitalistic attitude is based on this supposed transition we must examine it in some detail. He proceeds as follows: Some dog's blood collected in a test-tube is enclosed in a capsule of collodion open at one point. This is introduced into the peritoneal cavity of another dog, the open end of the capsule being in contact with the peritoneum. At the end of eight days the capsule is found to be completely encysted: the blood has clotted by the formation of radiating fibres of fibrin, but the opening of the capsule is plugged by a cork of fibrous tissue richly supplied by the host's blood-vessels. Now Nageotte maintains that the regularly arranged bundles of fibres of the fibrous tissue are produced by the gradual transformation of the radiating fibrin fibres; that the immigration of fibroblasts (*i.e.* connective tissue cells) is secondary, and finally that these elementary fibres can grow by intussusception from the fluid surrounding them. The whole of the supposed transition is based on the arbitrary inclusion of intercellular substance in the term living matter. Nageotte protests vehemently against what he terms the "exoplasmic theory," *i.e.* the view that this substance is the product of the secretion or bodily alteration of the exoplasm of the connective tissue cells; he terms it "the internal medium." But if he were an embryologist instead of merely a surgeon and an anatomist, he would see clearly that historically there is no other possible origin for his internal medium except the secretion of the surrounding cells: and he himself admits that subsequent changes in it only take place under the influence of living cells in the neighbourhood. Whether this influence is exercised, as he supposes, by the emission of ferments or by the production of secretion is a minor matter. If in company with the vast majority of histologists we regard the intercellular material as dead, then the validity of the supposed transition is destroyed.

Among the most startling of Nageotte's results is the discovery that it is possible to graft into a living animal a piece of connective tissue which has been preserved in alcohol or formaline. A piece of tendon thus treated introduced under the skin of the ear of a rabbit becomes invaded by the surrounding "fibroblasts"; its bundles of fibres become connected up at their ends with the surrounding connective tissue, and thus definitely incorporated in the skeletal framework of the ear. When a piece of dead cartilage is similarly treated still more curious results ensue. The neighbouring "fibroblasts" surround it and form a new perichondrium. These cells invade the capsules of the cartilage laid open by the section. These invading tongues burrow into the cartilaginous substance, forming cavities which they surround by newly formed *bone*, although there is normally no bone whatever found in the rabbit's ear.

If a segment of an artery of one dog preserved in alcohol be inserted between the cut ends of the artery of another dog, it becomes clothed with an endothelium: its layers of elastic and connective tissue become continuous with those of the artery of the other dog at both ends; and it becomes provided with new smooth muscle fibres, which appear from the transitional forms observed to be modifications of connective tissue cells.

We pass now to Nageotte's experiments with cut and regenerating nerves and nerve grafts. As all are aware,

there have been two leading theories of nerve structure. According to the older, nerves are formed by chains of cells the protoplasm of which becomes differentiated in place into nervous fibrils. According to the newer and almost universally accepted view, first firmly established by Ramon y Cajal, the nerve fibre or axon throughout all its length is the outgrowth of a single cell, the neurone or neuroblast. When it is cut the distal portion of the fibre, being separated from the influence of the nucleus contained in the neuroblast, undergoes "Wallerian" degeneration: the proximal stump grows out again into the old sheath, and so the fibre is regenerated. According to Nageotte, both theories are true. The axon, or, as he terms it, the "neurite," is the outgrowth of the neuron, but it can only grow along chains of ectoderm cells which constitute the sheath of Schwann. The only exception to this rule is when the axon reaches the ectoderm itself; in this medium it grows as a "naked" fibre. The medullary sheath belongs to the axon itself; it is produced by the confluence of mitochondria, and it is broken up and absorbed when the axon degenerates. When a nerve has been cut and the axons have degenerated, there ensues a rapid proliferation of the bands of ectoderm cells both at the proximal and distal sides of the cut: these bands form networks, and both cut ends may assume the aspects of swollen knobs. The upper of these is termed by Nageotte the "neurome," the lower the "gliome." The neurome becomes invaded by new axons; many of these get into lateral branches of the ectodermal network and never reach their destinations, but when neurome and gliome meet, as they eventually do, some axons penetrate the lower part of the nerve and so function is restored.

Nageotte has also established the remarkable fact that if a piece of a nerve be cut out and employed as a subcutaneous graft it becomes the centre of a nodule of firm, tough connective tissue, evidently showing that the cells of Schwann emit some substance which acts as a stimulus to the production of this kind of tissue. For this reason, when a long portion of a nerve has been lost and a graft is necessary to restore continuity, a graft of dead artery or tendon is often more effective than one of dead nerve.

The outstanding result of Nageotte's researches seems to us to be that the connective tissue cells have the power of acting as bone-cells, cartilaginous cells, "fibroblasts," or even smooth muscle fibres; according to the circumstances in which they are placed; that in Driesch's words the prospective fate of a cell is determined not by its nature but by its position — that "Ein jedes jedes kann" and this is a vitalistic conception, not a chemical or physical one.

E. W. MACBRIDE.

Early Mathematical Instruments in Oxford.

Early Science in Oxford. By R. T. Gunther. Part 2: Mathematics. Pp. 101. (London: Oxford University Press, 1922.) 10*s.* 6*d.* net.

THREE years ago a very interesting exhibition of early scientific instruments in Oxford was held at the Bodleian Library. A small printed list or catalogue of the exhibits was prepared at the time by Mr. Gunther, to whom all those interested in early scientific instruments are much indebted for bringing together the various early examples existing in the colleges of the University of Oxford, and making them available for inspection. It was intended that this small catalogue should form the basis of a more comprehensive work dealing with the history of science at Oxford, chiefly on the instrumental side. The first instalment (Chemistry) of this larger work was printed as a booklet in 1920 and afterwards published (see NATURE, March 3, 1921, p. 13). The second instalment, dealing with mathematics, has now been issued.

The stated object of Mr. Gunther's work is "to draw attention to such material objects of value as still remain to us, with a view to their better preservation, and to reviving the memory of the clever men who really helped science forward by the invention of practical methods, and by the cunning of their craftsmanship."

The first part of the booklet consists of "Notes on Early Mathematicians." One of the first mathematicians connected with Oxford was Daniel of Morley, who resided there in the year 1180, but went to the mathematical school at Toledo to complete his studies, and afterwards returned to this country as a teacher. The best known mathematician of this early period was the Yorkshireman, John of Holywood (Sacrobosco), who died in 1244. In the fourteenth century Richard of Wallingford, Thomas Bradwardine, John Maudith, Simon Bredon, John Ashenden, William Rede, and others, raised Oxford mathematics to a high level, and at that time "Oxford could boast more Mathematicians than any other country in Europe."

During the next century the study of mathematics was at a low ebb; in the middle of the century the only mathematical subjects required at Oxford for the master's degree in the *quadrivium* were the first two books of Euclid and the astronomy of Ptolemy. Cuthbert Tonstall (1474–1559) and Robert Recorde (1510?–1558), the only two English mathematicians of note during the first half of the sixteenth century, commenced their studies at Oxford, but found that they could continue them better at Cambridge, and

Mr. Gunther regards them as "the founders of what has been the most brilliantly successful mathematical school in the world."

Considerable space is given to Recorde's work, and it is remarked that "although Recorde was a Fellow of All Souls, yet two years back his name was quite unknown there, and not one of his numerous printed books is in the College Library." It has been possible, however, from existing documents, to reconstruct the catalogue of Recorde's private library, and this is given. The first section closes with references to the work of Edmund Gunter (1581–1626), William Oughtred (1574–1660)—not an Oxford man, but a clever mathematician who "appears to have given private tuition in mathematics to many Oxford men,"—Christopher Wren (1632–1723), Seth Ward (1617–1689), John Wallis (1616–1703), and Nathaniel Bliss, who was Savilian professor of geometry from 1742 to 1765.

FIG. 1.—Cista Mathematica. By the courtesy of the Librarian of the Bodleian Library.

The second part consists of a descriptive list of early mathematical instruments belonging to the University and colleges of Oxford, including some allied instruments in the collections of the Royal Society, Mr. Lewis Evans—whose large and valuable collection, at present exhibited in the Bodleian, is now offered as a gift to the University (see NATURE, December 9 and 16, 1922, pp. 783, 828),—and a few others. Of special interest is the seventeenth-century oak chest—*cista mathematica* (Fig. 1)—in the Bodleian Portrait Gallery, which originally contained the various demonstration models of the Savilian professors, as detailed in the 1697 catalogue of the Bodleian Library. In spite of its three different locks, the only portions of the original equipment now remaining are two small beechwood spheres. Other interesting objects described are the "Circles of Proportion" of Oughtred, and the instruments from the Orrery collection in Christ Church College. This collection, which consists of elegant examples of the work of John Rowley and others at the beginning of the eighteenth century, has been "shut up in a cupboard" since 1731, the year in which it came to Christ Church as part of a bequest of Charles Boyle, fourth Earl of Orrery.

The excellent condition of most of these instruments affords ample testimony to the efficiency, in this instance, of the "shut cupboard" method of preservation. Unfortunately, this happy result is exceptional, the more usual experience being of the Mother Hubbard type. Such collections, formed so that posterity may be able to see actual examples of the fine work performed by makers in the past, in some way or other often dwindle, disperse, or disappear. Various causes—war, fire, the carelessness or ignorance of a custodian, exigencies of space required for other purposes, the transference of such objects from one department to another concerned only with modern developments and with no sense of the high value of actual early instruments as original documents—tend to produce such a result. Experience in all countries shows that the safest and most efficient way to preserve such specimens of the work of men who have played a big part in the development of modern civilisation is to exhibit them under the proper conditions of security afforded by a national museum, so as to be available continuously for inspection. A Museum of Science should be rich in such objects, which testify in a very real manner to the state of advancement in past times in the art of constructing scientific instruments.

The last part of Mr. Gunther's book consists of short notes, arranged in chronological order, on mathematical instrument makers from the latter part of the sixteenth to the early part of the nineteenth century. We look forward with interest to the publication of the next instalment, which will deal with astronomy at Oxford.

Our Bookshelf.

Principles and Practice of Butter-Making. By Dr. G. L. McKay and Prof. C. Larsen. Third edition, largely rewritten. Pp. xiv+405. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1922.) 15*s.* net.

THE volume under notice is the third edition of one of the best-known American books on commercial butter-making; it deals with the subject with great thoroughness, and contains information which has been collected from the best sources. The introductory chapters give an account of the composition of milk, its secretion, and the conditions which influence secretion. Next come the properties of milk, and these are followed by an account of the changes which milk undergoes when heated. In an account of the peculiarities of butter fat, stress is laid upon the great value of this fat in nutrition, owing to its content of the fat soluble vitamin A. There are chapters on the enzymes and bacteria found in milk, and the causes which induce variations in the percentage of fat.

Sampling and testing of milk and cream, both from the point of view of fat content and suitability for butter-making, are dealt with, and the best creamery methods for the estimation of fat in butter are given, while there are also chapters dealing with modes of payment for milk and cream delivered to the factory.

The various types of separators and the best means of separating milk naturally occupy a prominent place, and the preparation of the cream for churning is fully discussed. Excellent chapters are written upon the churning, working, washing, and finishing of butter from the point of view of creamery practice. Packing and marketing of butter; defects and their causes; judging and grading; storing, particularly cold storage (descriptions of the plant are also given), are all dealt with fully.

Handbook of Commercial Geography. By Geo. G. Chisholm. New edition. Pp. xvi+824. (London: Longmans, Green and Co., 1922.) 25*s.* net.

ALL geographers and economists will welcome this new edition of Mr. Chisholm's well-known work with its scrupulous accuracy of detail. The previous edition was published eleven years ago: the present, a ninth edition, was almost ready when war broke out in 1914. The necessary delay in publication has enabled Mr. Chisholm to revise the book according to the present condition of the world. The book has been reset throughout, which has allowed the incorporation in the proper places in the text of the matter in several of the introductions of earlier editions, and the chapter on trade routes. The section on the British Isles has been extended considerably. Several new maps have been added including rainfall and actual temperature charts. The valuable statistical appendices have been revised to 1913 and increased in number. A new feature is a long list of alternative geographical names. While the book has grown, its well-known features remain unchanged, and few works of reference are better arranged or indexed than this standard volume on commercial geography. It is a monument of painstaking research, clear thinking, and encyclopædic knowledge, indispensable not only to every serious student of geography and economics, but also to all engaged in trade and commerce.

The Canary Islands: Their History, Natural History, and Scenery: An Account of an Ornithologist's Camping Trip in the Archipelago. By D. A. Bannerman. Pp. xvi+365+pl. (London: Gurney and Jackson, 1922.) 30*s.* net.

THE problems presented by insular faunas and floras are of the greatest interest both to the student of geographical distribution and to the geographer. Chapters V. and VI. of this rather uncomfortably heavy book deal respectively with the affinities and origin of the Canarian flora, the modes of dispersal of the trees and plants, the distribution of animal and bird life in the Canary Islands, and some problems which they suggest. The author gives numerous examples of the influence of complete isolation on the differentiation of birds no longer able to interbreed with the continental stock from which they sprang; and in some cases, *e.g.* that of the Fuerteventura bustard, is able to suggest how the local conditions may have contributed towards the selection of geographical subspecies. The chapters on the origin, geology, and physical characteristics of the islands are convenient summaries for the general reader, while references to larger works and original papers will enable those who wish to consult the first-hand authorities.

Les Maladies parasitaires des plantes (Infestation-Infection). Par M. Nicolle et J. Magrou. Pp. 199. (Paris: Masson et Cie, 1922.) 8 francs.

Two doctors of the Pasteur Institute have collaborated on the production of a text-book chiefly for the benefit of the medical profession. The ground covered is very wide, including diseases due to both insects and fungi. Part I. deals largely with gall formation, with short chapters on acarids and nematodes. The remaining parts give an outline of the diseases due to phanerogams, fungi, and bacteria, with a general discussion of such questions as virulence of attack and resistance to disease. The complete absence of illustrations is a very serious drawback, even though it be considered necessary on account of cost. A further disadvantage is the lack of a bibliography, which would partly have compensated for the very brief treatment of each subject. In other ways the book is well produced and will serve a useful purpose in making information on plant diseases available to medical men.

Clocks and Watches. By G. L. Overton. (Pitman's Common Commodities and Industries Series.) Pp. ix+127. (London: Sir Isaac Pitman and Sons, Ltd., 1922.) 3*s.* net.

MR. OVERTON has given us a most useful and interesting volume, describing the gradual evolution of time-pieces from the early water clocks, through the balance clock, down to the modern pendulum clocks and chronometers. There are many illustrations, and the various methods of compensating for temperature are described in plain non-technical language. In addition there are details, probably new to many readers, relating to the striking mechanism of clocks and of repeater watches. The latter are stated to have come

to an end when the introduction of lucifer matches made it easy to read an ordinary watch at night. There is a chapter dealing with the artistic side of the subject, and describing several clocks and watches of special interest and beauty. It is altogether a book that will appeal to the general reader quite as much as to those specially interested in time-determination. A. C. D. C.

Anthracite and the Anthracite Industry. By A. Leonard Summers. (Pitman's Common Commodities and Industries Series.) Pp. x+126. (London: Sir Isaac Pitman and Sons, Ltd., 1922.) 3*s.* net.

THIS book seems to be a combination of a scientific manual and a coal-dealer's propaganda circular. With some useful information about anthracite, we find other matter—on p. 26 a statement that in 1921 the South Wales coal-owners were losing 25,000,000*l.* a year because of "unwanted young men—'hot-heads' and agitators" in the mines—an example of "what the industry is up against"; on p. 69 we have a series of testimonials in the approved style, and "tourist facilities in the beautiful anthracite district" in Chapter II. The printing of advertisements on the reverse of the title-page is also distracting. When information about anthracite is encountered in the book it proves interesting, but some patience is required to find it. "Tar," we are told on p. 112, "also contains chemicals, such as carbolic acid and saccharine."

Polarity. By Geoffrey Sainsbury. Pp. 48. (London: The Favil Press, Peel Street, W. 8., 1922.) 3*s.* 6*d.*

MR. SAINSBURY'S artistically printed little book consists of a series of short essays on sex, religion, education, society, and ethics. The point of view of the author is unusual and independent, and it demands that the reader's mind should free itself from many placidly accepted concepts. Polarity, the author thinks, has never been adequately considered, as man invariably tries to bring the problem of life and all attendant problems down to a single issue. Polar conflict is to be seen everywhere, and innumerable problems hinge upon this relationship and to none of this type can there be any final answer. There is also a plea for a willingness to see knowledge from a more general, instead of the extremely specialised, point of view. There will be many readers who will dissent from the views here set forward, which will certainly stimulate thought.

Man—The Animal. By Prof. W. M. Smallwood. Pp. xv+223. (New York: The Macmillan Co.; London: Macmillan & Co. Ltd., 1922.) 12*s.* net.

PROF. SMALLWOOD'S little book is interesting but confessedly "popular," and therefore fraught with the difficulties that are inseparable from all "popular" presentations. Its object is to summarise the discoveries of recent years, to indicate some of their relations to the more fundamental problems of man's physical existence, and to give a deeper insight into the characteristics which man has in common with all life, and which exercise a profound influence on his entire existence. The chapters on reproduction, heredity, the problem of learning, and biology and progress are especially well done. The whole book, though not absolutely free of error, is worth reading, and will be especially appreciated by readers possessed of biological knowledge.

Chemistry and its Uses. A Text-Book for Secondary Schools. By W. McPherson and W. E. Henderson. Pp. viii+447. (London: Ginn and Co., 1922.) 7*s.* 6*d.* net.

THE text-book before us is intended for use in American high-schools, and would probably be very suitable for that purpose. It is written from the point of view of the patriotic American, and naturally refers principally to American conditions. There are some reproductions of portraits of well-known chemists. Each chapter is provided with exercises, and a rough equality of division is adopted between pure and applied chemistry (including organic chemistry, treated very superficially). There are numerous illustrations of labelled bottles: even assuming that these contained what is represented when they were photographed, the value of the pictures is not at all clear. Surely it is not intended that they shall replace actual acquaintance with real substances? The actual text is clear and accurate, so far as it was examined, and the book would interest English teachers.

Chemistry for Beginners and Schools (with Glossary). By C. T. Kingzett. Fourth edition. Pp. vii+237. (London: Baillière, Tindall and Cox, 1922.) 5*s.* net.

THE continued demand for Mr. Kingzett's book indicates that it is serviceable to numbers of readers. It is clearly written, and contains many interesting experiments. The glossary will also be found useful by beginners; surely, however, "lixiviate" is commoner than "lixurate" (p. 212)? The section on "Force and Energy" (pp. 34-52) requires revision. It is very much out-of-date in parts, and not up to the standard of the rest of the book: the statement that "electricity, like heat and light, is a form of force" (p. 45), although it may have been true for Faraday, is not so to-day. The book is scarcely suitable for schools, as it provides no systematic course—the experiments are introduced at random.

Concrete and Reinforced Concrete. By W. N. Twelvetrees. (Pitman's Common Commodities and Industries Series.) Pp. x+137. (London: Sir Isaac Pitman and Sons, Ltd., n.d.) 3*s.* net.

THE general reader will find a great deal of interesting matter in this book, which is explanatory and practically free from calculations. Sufficient is given to make clear the nature of the materials employed and their combination, and the author has included a number of examples of finished work which convey a very good impression of the extent to which concrete and reinforced concrete have been employed, and of their possibilities. There are some historical notes, from which we gather that the ancient Egyptians were thoroughly familiar with concrete, as is proved by a fresco in the temple of Ammon at Thebes, depicting hieroglyphically the making and use of concrete in the year 1950 B.C.

On the Missing Element of Atomic Number 72.

SINCE Moseley's discovery of the fundamental laws of the X-ray emission, it has become quite clear that the most simple and conclusive characteristic of a chemical element is given by its X-ray spectrum. In addition, Moseley's laws allow us to calculate very accurately the wave-lengths of the X-ray spectral lines for any element in the periodic table, if those of the elements in its neighbourhood are known. Taking into account that the presence of a very small proportion of a definite element in any chemical substance suffices to give a good X-ray spectrum of this element, it is quite evident that for the eventual discovery of any unknown element X-ray spectroscopy, especially as it has been developed by Siegbahn, represents the most effective method.

In the *Comptes rendus* of the Paris Academy of Sciences for May 22, 1922, Dauvillier announced the detection by means of X-ray spectroscopy of the element 72 in a mixture of rare-earth metals. This element was identified by Urbain with a rare-earth element, which he called celtium, the presence of which he had previously suspected in the same sample. For different reasons, however, we think that Dauvillier's and Urbain's conclusions are not justified. It appears from Dauvillier's paper that at any rate the quantity of the element 72 in the sample, if present, must have been so small that it seems very improbable that the element 72 should be identical with the element which in former papers Urbain claims to have detected in the same sample by investigation of the optical spectrum and of the magnetic properties. The only lines which Dauvillier claims to have detected are the lines La_1 and $L\beta_2$, both of which he finds to be extremely faint (*extrêmement faible*). The wave-lengths he gives, however, for these lines are about 4 X.u. (1 X.u. $= 10^{-11}$ cm.) smaller than those which are obtained by a rational interpolation in the wave-lengths tables of Hjalmar and Coster, for the elements in the neighbourhood of 72.

From a theoretical point of view it appears very doubtful that the element 72 should be a rare-earth. It was announced in 1895 by Julius Thomsen from Copenhagen that from general consideration of the laws of the periodic system we must expect between tantalum, which in many compounds possesses 5 valencies, and the trivalent rare-earths, a tetravalent element homologous to zirconium. The same view has also recently been put forward by Bury on the basis of chemical considerations, and by Bohr on the basis of his theory of atomic structure. It is one of the most striking results of the latter theory, that a rational interpretation of the appearance of the rare-earth metals in the periodic system could be given. For these elements, according to Bohr, we witness the gradual development of the group of 4-quantum electrons from a group containing 18 electrons into a group of 32 electrons, the numbers of electrons in the groups of 5- and 6-quantum electrons remaining unchanged. Bohr was able to conclude that in the element lutecium (71) the group of 4-quantum electrons is complete, and we consequently must expect that in the neutral atom of the next element (72) the number of electrons moving in 5- and 6-quantum orbits must exceed that in the rare-earths by one. The element 72 can therefore not be a rare-earth but must be an homologue of zirconium.

In view of the great theoretical importance of the question we have tried to settle it by an experimental investigation of the X-ray spectrum of extractions of zirconium minerals. We have succeeded in detecting six lines which must be ascribed to the element 72 (in Siegbahn's notation La_1, α_2, β_1, β_2, β_3, and γ_1). The complication was met that the lines La_1 and α_2 lie almost exactly in the place corresponding in the spectrum to the zirconium $K\alpha_1$, and α_2, lines in the second order. Difficulties which might arise from this fact may easily be avoided by keeping the tension on the tube between the critical tension of the zirconium K-lines (18,000 volts) and that of the L-lines of the missing element (10,000 volts). Besides, the relative intensity of the $K\alpha$ lines is so different from that of the two $L\alpha$ lines that any ambiguity is already thereby excluded. Not only the $L\alpha$ lines but also the lines $L\beta_1$, β_2, and β_3 were, as regards their mutual distance and their relative intensity, in exact agreement with the expectation. The values which we obtained for the wave-lengths of the six mentioned lines all agree within one X.u. with those found by interpolation. Between our values for the lines La_1 and $L\beta_2$, and those published by Dauvillier, however, there exists the discrepancy referred to of about 4 X.u. (in general for other elements which have been measured by Dauvillier and by Coster the discrepancy is never more than 2 X.u.). Exposures under different conditions as well as a thorough discussion of the plates showed that the new lines found during our investigation cannot be ascribed to the first or higher order spectrum of any other known element. Our provisional results are: $La_1 = 1565{\cdot}5$; $\alpha_2 = 1576$; $\beta_1 = 1371{\cdot}4$; $\beta_2 = 1323{\cdot}7$; $\beta_3 = 1350{\cdot}2$; $\gamma_1 = 1177$ X.u. More accurate and complete data as well as photographs of the spectrum will soon be published.

In a Norwegian zirconium mineral the new lines were so intense that we estimate the quantity of the element 72 present in it to be at least equal to one per cent. Besides we investigated with low tension on the tube a sample of "pure zirconiumoxyde." Also with this specimen the $L\alpha$ lines were found, but very faint. It seems to be very probable that ordinary zirconium contains at least from 0·01 to 0·1 per cent. of the new element. Especially the latter circumstance proves that the element 72 is chemically homologous to zirconium. Experiments are in progress to isolate the new element and to determine its chemical properties.

For the new element we propose the name Hafnium (Hafniae = Copenhagen).

Continental Flotation and Drift.

THE theory that the continents have shifted their positions during geological time and, possibly, are still in motion has lately excited much discussion. The principal obstacle to its acceptance is the difficulty of adducing a force adequate to bring about the movements. Many years ago Osmond Fisher ("Physics of the Earth's Crust" p. 339) ascribed general continental movements of this kind (accounting for the Atlantic rift, etc.) to the disturbance of the Pacific basin due to the genesis of the moon, on Darwin's well-known theory. Lately, Wegener has brought forward much evidence in favour of continental movements. But I do not think he has

discovered any adequate source of the motion. The *polefluchtkraft* is too feeble; it is purely meridional in direction and is inconsistent with the existing distribution of the land. It is probably ineffective. A differential soli-lunar attraction on the emergent features of the continents is obviously inadequate. The fact is Wegener works out the theory on the basis of a westerly drift of the continents. In doing so I think he is in error. An adequate force appears available provided an easterly drift is postulated; and so far as I can see the theory grows in probability when examined from the new point of view.

According to Sir George Darwin, the tidal effects of sun and moon acting on "a stiff yet viscous planet" ("The Tides," p. 277) must produce a retardation of the surface crust relatively to the interior. He states that this is speculative as regards the earth; but this was written twenty-five years ago. The great fact of the isostatic compensation of the continents, proving their flotation in a viscous magma, was not then supported by such strong evidence as Hayford and others have since adduced. I assume that the differential motion exists (or formerly existed) and that the floating continents possess a slightly less rotational velocity than the deeper parts of the underlying magma, the velocity of which continues to increase downwards until a more rigid interior is reached.

The consequence of this assumption is that the eastern velocity of every land area on the globe depends to some extent upon its downward penetration into the sustaining magma. A continent upon which a great geosynclinal loading is progressing becomes acted upon by the faster moving layers and is exposed to a force which is continuous and relentless, and the intensity of which depends on the area and depth of the protuberance. Whether the resultant motion of the continent will be due east, relative to the surface crust, or whether it will take up a turning or rotational motion, will depend on the location of the applied force. If excentric a rotational movement must ensue. If uniform over the continental area—as in the case of a great "revolution" or oceanic invasion—the drift will be towards the east.

According to this view, America did not leave Europe and Africa but was left behind by them. Their increased easterly velocity was, possibly, ascribable to the great Laramide submergence of South Europe, South Asia, and North Africa. (The tidal effect is greatest in equatorial regions.) In a similar manner New Zealand left Australia: the force in this case being plainly referable to the isostatic compensation demanded by the lofty ranges of New Zealand. So also Ceylon was torn from Peninsular India; the fracture line of the eastern Asiatic coast was produced, etc.

As regards mountain elevation it is evident that, while from the present point of view mountain building is in every case ultimately referable to tidal forces, mountains may develop in different circumstances. They may, in central continental areas, be conditioned partly by magmatic pressure from beneath, partly by crustal pressure. In such a case as the western mountains of America the magmatic pressure eastwards must be the principal agent. The continental movement gives rise, in this case, to a depression of the bordering ocean floor—a "wake." But, again, continental movements may give rise to mountain chains by the direct pressure between land masses. In this manner the Himalayan chains probably originated. The force arising out of the compensation required by the great and lofty central plateaus of Asia sufficiently accounts for a turning movement around the more stationary features of Peninsular India and the Arabian Plateau. This is in harmony with the current view that the fold-mountains of Asia were diverted by the resistance of those massive earth blocks.

J. JOLY.

Trinity College,
Dublin, December 31.

SINCE my return from the Falkland Islands a few months ago I have followed with great interest the course of the discussion in the columns of NATURE which has ensued upon the publication by Prof. Wegener of his revolutionary views on the flotation and drifting of continental masses. During my recent geological survey of the Falkland Islands I was very greatly impressed by the extraordinary similarity of the geology of the Islands to that of Cape Colony. The geological succession comprises rocks ranging in age from Archæan to Permo-Carboniferous, although rocks of Cambrian, Ordovician, and Silurian age appear to be absent. The oldest rocks closely resemble some of the Archæan rocks of Cape Colony; and from the Devonian to the Permo-Carboniferous the lithological and palæontological succession is practically identical in the two areas. The post-Triassic dolerite dykes of the Falklands are also very like the intrusions of the same age in Cape Colony. The east and west folding so evident in the southern part of Cape Colony makes the most conspicuous feature in the Falkland Islands. The only notable point of difference in the two areas is that whereas in Cape Colony the lowest division of the Cape System (Devonian), namely the Table Mountain Series, is much folded, the corresponding rocks in the Falkland Islands have escaped such disturbance and lie almost horizontal, or with only a gentle dip, over an area of many square miles. The equivalents of the middle and upper members of the Cape System (Bokkeveld Series and Witteberg Series) are, however, intensely folded in the Falkland Islands.

From the orthodox point of view one has to believe in the persistence, in minute detail, of a stratigraphical sequence representing the passage of a great period of geological time, across the 5000 miles of ocean which separate Cape Colony from the Falkland Islands, and, in face of the array of facts marshalled into such an orderly and effective host by Wegener and again by Du Toit, this becomes, on a sudden, an unexpected strain upon one's faith.

In discussing the ice-fields of Gondwanaland in his very interesting paper, "Land Connections between the Other Continents and South Africa in the Past" (*S. Afr. Journ. Sci.*, pp. 120-140, Dec. 1921), Dr. Du Toit states that in the Falkland Islands the centre of origin of the ice is unknown. I was able, during my survey of the Islands, to note that wherever the glacial tillite at the base of the Permo-Carboniferous sequence was adequately exposed it was always possible to collect a varied assortment of rocks occurring as erratic boulders in the deposit, and certain types, such as pegmatite, a coarse granite, and a pink quartzite, never failed to occur. The one and only exposure of Archæan rocks in the Colony occurs at Cape Meredith, the southernmost point of West Falkland, and when I examined that area I readily recognised the pegmatite, granite and quartzite occurring there as similar to the ubiquitous boulders of the tillite. Subsequent microscopic examination confirmed the identity of the rocks.

With regard to the direction of the striæ on glaciated surfaces underlying the tillite, I never came across a really convincing exposure, but in a few places on both East and West Falkland I noted, on the smoothed surface of the quartzite beneath the tillite, what I regarded (although with some doubt) as glacial striæ, and in every case the markings ran

about N. and S. (magnetic). The evidence suggests movement of the ice from south to north, but we have no knowledge as to whether there did not exist, in Palæozoic times, an exposed mass of ancient rocks to the northward of the present Islands.

The Determination of *p*H of Microscopic Bodies.

NEUTRAL red has the almost unique property of being both an intra-vitam stain and a fairly good indicator. It has also low salt and protein errors, as Homer has shown (1917, *Biochem. Journ.* 11, p. 283).

If therefore cells are stained with neutral red, the colour of the stain as observed with the microscope enables one to judge roughly the *p*H within the cell.

Working on certain marine protozoa, I have found a method of greater accuracy than that of merely judging the colour as seen down the microscope. The method is simple and, so far as I am aware, has not been recorded before.

A series of tubes containing solutions of increasing *p*H is made up in the ordinary way, and a few drops of neutral red are added as indicator. A stout cardboard strip is taken and holes are cut in it at intervals so that the strip will carry the series of tubes (each tube fitting tightly).

The strip with the tubes hanging freely below it is now suspended in the window. With the aid of the microscope condenser the series is focussed sharply in the plane of the object which is being examined.

The appearance down the microscope now consists of the stained object and by its side the image of the series of tubes: both are seen against the same background of sky. By simply tilting the mirror the images of successive tubes of different *p*H can be brought into juxtaposition with the object examined. In this way the *p*H of the stained body can be determined by direct comparison.

I have found that the *p*H determined by the above method can be checked roughly as follows. The mirror is tilted so that the image of one of the tubes forms a background against which the object is seen. In these circumstances the object is illuminated by light of the particular quality corresponding to the colour of the tube. A succession of tubes is used in this manner as a background for the object.

When the background transmits the same quality of light as the stained object, the latter appears relatively light and transparent: this occurs when the colour of the object and the background correspond to the same *p*H. If the object is illuminated by light from a tube of higher or lower *p*H, the object appears darker owing to the fact that the light transmitted by the background is not exactly of the same quality as the light transmitted by the object. The *p*H of the background tube against which the object appears lightest corresponds to the *p*H of the object.

It must be admitted that the colour change with the *p*H in the case of neutral red does not render the latter an ideal indicator for the second method, but the effect is quite good enough to be used as a check. Perhaps a better intra-vitam indicator will be discovered in the future, and in that case the method might be developed to a fair degree of accuracy.

In all this work a good achromatic condenser is essential, for the diaphragm must be widely open in order that the colours of both the object and the image of the tubes may be well defined.

When the light is bad or when artificial light is used, the definition of the colours is greatly increased if the light is first filtered through a dilute solution of copper sulphate. Using this filter, the red tint due to the presence of acid appears darker and is more easily seen in lightly stained bodies.

C. F. A. PANTIN.
The Marine Biological Laboratory,
Citadel Hill, Plymouth, December 14.

Divided Composite Eyes.

IT would appear from Mr. Mallock's letter (NATURE, December 9) that our knowledge of the Aleyrodidæ or "White Flies" is not so exact as it might be. This, however, takes too pessimistic a view of the situation. Whilst, undoubtedly, much remains to be done, even with some of the British species, the specific limits of those to which he refers are quite well known to students of the group. Indeed, as a result of my own researches I have been able, in recent communications to the *Entomologist* and the *Vasculum*, to assign our British species to no fewer than four distinct genera, Aleyrodes, Tetralicia, Aleurochiton, and Asterochiton, and the forms mentioned by Mr. Mallock reveal themselves as comprising two genera and three species, namely, *Aleyrodes proletella* L., *A. brassicæ* Walk., and *Asterochiton vaporariorum* West.

Clearly, as no hint is given that any of his insects were bred from *Chelidonium majus*, the figures given cannot represent *A. proletella* as indicated by the legend; they must be referred either to *Aleyrodes brassicæ* or to *Asterochiton vaporariorum*. If *A. brassicæ* is the insect intended, then as a larva it feeds on cabbage, as a pupa it lacks well-developed dorsal papillæ, and in the perfect condition has spotted wings with the median nervure appearing as a short spur. On the contrary, the larvæ of *Asterochiton vaporariorum* can be collected from any of the plants enumerated, its pupæ have dorsal papillæ, and its imago possesses immaculate wings displaying no trace of the media.

To the latter insect belongs the notoriety gained by the so-called "White" or "Tomato" fly during the past twenty years. Unfortunately, this Aleyrodid, although a native of neotropical regions, is so adaptable in its food habits as to be nearly polyphagous and, furthermore, has acquired the habit of wintering at ordinary air temperatures even in this rather bleak locality on the north-east coast. A colony with which I was experimenting in 1921 successfully withstood all the frosts of the winter of 1921–22, the first brood of the present season emerging in May.

A further point I cannot understand is Mr. Mallock's comparison of the life-cycle of the Aleyrodidæ with that of the Aphididæ. So different are the two cycles that I feel sure that some mistake has arisen here. In every detail of their structure and life history their affinities lie rather with the Psyllidæ (particularly with some of the Triozæ possessing scale-like larvæ) or toward the Coccidæ.

Finally, I should like to point out that I am preparing a monograph of the British Aleyrodidæ and should therefore be extremely glad to receive species of the group, more especially if they are accompanied by their respective larvæ and pupæ.

J. W. HESLOP HARRISON.
Armstrong College, Newcastle-upon-Tyne,
December 12.

I AM obliged to Dr. Harrison for remarking on the mistake in my letter in NATURE of December 9 where in one place "Aphides" was written instead of "Coccidæ." The specific name *proletella*, placed under the outline sketch in Fig. 1 *a*, was given on the authority of a well-known entomologist to whom specimens were sent for identification. Dr. Harrison would name this *brassicæ*.

With regard to the number of genera and species to which he refers, the present tendency seems to be to multiply both unnecessarily. Among the various Aleyrodids which I examined there appeared to be considerable variation, and it was possible to collect from the same plant specimens differing in size from large to small through many gradations and having wing spots either well marked or nearly evanescent.

The difference between "species" and "variety" is one of degree, but specific difference may be claimed for races which have so diverged that a fertile mixed race cannot be produced from them. Whether this condition is satisfied in any particular case can only be determined by rather laborious trials, but in the absence of evidence of this kind it would be more correct, and certainly more convenient, while noting small differences (which may be constant in certain circumstances and localities) to treat them as varieties. A. MALLOCK.

9 Baring Crescent, Exeter,
December 21.

Science and Armaments.

I DESIRE to direct the attention of readers of NATURE to a matter which I think to be of importance. During the war of 1914–18 a great number of scientific men, other than those in the medical service, were engaged on work which was devoted entirely to military ends.

Since the armistice there has been some tendency, not unnatural perhaps, to confuse this war work with other researches carried out directly in the service of science. In the Science Library, South Kensington, cheek by jowl with works on atomic theories or relativity, are found such books as one on the organisation of the Army Signal Service, and another on poison gas warfare which adopts most successfully the language of a scientific text-book. In the publications of certain learned societies, nominally concerned with purely scientific aims, are found descriptions of instruments and investigations of almost purely military interest. The collection of war material at the Crystal Palace is shortly to displace the priceless collection of historical apparatus and instruments from the Western Galleries of the Science Museum; the instruments are to go into storage, in a place where they will be inaccessible to the general public, for an indefinite period.

The lamentable implication seems to be that the development of armaments now holds a recognised place as one of the worthiest aims of science, but that is a doctrine which, I trust, is still very much open to question. It is more probable that we simply lack good taste and a proper appreciation of relative values.

I venture to suggest that science would be best served by keeping these things separate. If necessary, let the Government extend a military museum to house such of the material from the War Museum as possesses real interest from the military point of view; it should not be allowed to displace a single instrument from the historical collections. Let us also refrain from filling our library shelves with matter of the kind previously indicated. So may the temple of science be kept free from echoes of human quarrels.

The example of the British expedition sent, in spite of the war, to test the Einstein effect has often been quoted as an outstanding example of the wonderfully dispassionate internationalism of science, but it scarcely bears comparison with the events of a hundred years ago when Davy, taking Faraday as his assistant, travelled to Paris to lecture during the height of the Napoleonic wars. We have gone far since those days—In which direction? L. C. MARTIN.

Imperial College of Science, South Kensington.

Waterspouts.

WITH reference to the letter from Dr. Hale Carpenter (NATURE, September 23, p. 414) describing an interesting waterspout seen over Lake Victoria, a letter has been received in the Meteorological Office from Mr. H. E. Wood, of the Union Observatory, Johannesburg, describing the development of a cloud pendant seen by him on the afternoon of November 19, 1922. The following extract from Mr. Wood's letter describes the occurrence:

"The day was a particularly calm one, the morning was hot with a fairly clear sky, but early in the afternoon there were many cumulo-nimbus clouds in the sky. I noticed particularly the uniformity in the base-level of all the clouds. Just about 3 P.M. I noticed a little pendent cone under one of these clouds and, having seen a waterspout here once before (in 1910) thought this might become one and decided to watch it. The waterspout developed rapidly and I got Mrs. Wood to make a series of drawings of it. Unfortunately the waterspout was rather too far away for photography—it would have been very small taken with an ordinary camera and I had no telephotographic lens available. The interesting feature of the waterspout seemed to me to be the detail of the earth-end (as shown in Fig. 1 reproduced

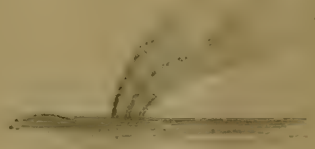

FIG. 1.

from a sketch made at 3.15 P.M.): there was a well-marked "core" surrounded by a less dense sheath. It did not rain in the vicinity of this spout until some time afterward; so that the lower part would probably consist of dust. Later we saw a series of waterspouts in the same vicinity. We estimated (when this particular cloud became an active thunderstorm) that the distance of the waterspouts was about 8 miles and hence that the length of the column or height of the cloud base was about 3700 feet."

The phenomenon noted by Mr. Wood is very similar to that noted by Dr. Hale Carpenter, except that in the present case the part shown in the sketch is probably due mainly to dust raised by the whirl. It is possible, however, that the greater density of the central core is due to condensation of water vapour.

D. BRUNT.

Meteorological Office, Air Ministry,
December 23.

I STOOD watching the effects of an ordinary small whirlwind when a Swahili volunteered the information that similar phenomena were at times to be seen over the sea, but that, in those cases, what one saw was God (*Muungu*) drawing a whale (*nyamgum*) aloft.

Most Swahilis have only a shadowy conception of what a whale is; to them it is a great snake which devours men and even boats. When God is angry with one of these beasts, he lets down a rope by which the monster is caught and drawn struggling to heaven. H. E. HORNBY.

Mpapua, Tanganyika Territory,
November 21.

The Cause of Anticyclones.

IN NATURE of December 23, 1922, p. 845, Mr. W. H. Dines points out that the main features of the pressure distribution of the atmosphere are of a permanent character, and, strange to say, the great areas of low pressure are over the cold poles, while the two belts of high pressure are on both sides of the equator in latitudes 30° or thereabouts; and, so far as the troposphere is concerned, the atmosphere is warm over areas of high pressure. Mr. Dines remarks, "The difficulty should be faced and not ignored."

At the Royal Society, on November 23 last, I had the pleasure of hearing a paper read by Lindemann and Dobson, who have succeeded in determining the temperature of the upper atmosphere (stratosphere) by observations of the luminosity of meteors. They estimate that at a height of 60 km. the temperature of the air is in the neighbourhood of 300° Abs.

In a paper communicated to the *Phil. Mag.* (vol. xxxv., March 1918, p. 233) I gave a diagram showing the probable temperature of the atmosphere between the poles and the equator up to heights of 70 km. This diagram was constructed by plotting the temperatures ascertained by sending up self-registering balloons, and extrapolating for greater heights. At the poles the temperature arrived at was about 285° Abs. at 60 km. In the paper referred to I concluded that the stratosphere over the poles and equator is much hotter than it is over the high pressure belts at latitudes 30° N. and S. of the equator —20° C. or more—and suggested that the winds of the earth are very largely affected by these differences of temperature.

The temperature values found by Lindemann and Dobson showed considerable variations when the results obtained by one falling star were compared with another. I would suggest that the several results they obtained be plotted on a diagram, the ordinates being temperatures at 60 km. and the abscissæ barometric pressures. Knowing the time and position of each falling star, the pressures could be obtained from meteorological charts. My suggestion was that the upper atmosphere is hotter over low pressure areas than it is over high pressure areas.

Soil Reaction, Water Snails, and Liver Flukes.

IN NATURE of November 25, p. 701, Dr. Monica Taylor mentions that the distribution of *Limnæa truncatula* in S.W. Scotland is very local, being rare or altogether absent from certain districts in which sheep are known to be infected with liver flukes. In such districts *L. peregra* is found infected with perfectly developed cercariæ of *Fasciola hepatica*. Free active cercariæ of the latter are also found.

In NATURE of December 23, p. 845, Mr. R. Hedger Wallace directs attention to the prevalence of liver fluke disease in the Swansea valley, where rough pastures have been limed. He asks, "Does liming a wet sour pasture make it more congenial to the water snail?"

For the past year, as occasion permitted, we have been engaged upon the study of the distribution of snail species in relation to the hydrogen ion concentration of the soil and water. A very striking limitation is found for certain species, and but few are found in the more acid habitats. Thus, over quartzite at *p*H4·8, nothing but a few Hyalinias could be found, whereas around *p*H7 numerous species exist, including *L. truncatula*. Fewer species are found at *p*H8, but those that do are often in great numbers, *Helicella caperata* and more especially *H. virgata*. Upland peat soil is usually close to *p*H4·6, and rough pastures may be between that and *p*H5·4 or somewhat over, so it seems highly probable that liming such land, by bringing it to the neighbourhood of *p*H7, does make the conditions more favourable for the snails concerned in the transmission of the disease.

In cases where certain sheep in a flock are infected, it would seem advisable to drive the flock to the most acid soil available, provided it is strongly acid, for in such a site the infected sheep will not be able to infect others, and so the disease may be stamped out or reduced in amount.

Where the neutral or slightly acid soil which appears to favour the occurrence of liver fluke disease is wanting, transference to chalk or limestone soil, at about *p*H8, may perhaps be equally effective; but it must be remembered that, owing to leaching by rain, the steep places in such districts may be less alkaline, or even acid.

It is very desirable that the limits of distribution of *L. truncatula* and *L. peregra* should be defined in relation to the reaction of the soil and water, and the writers would be glad to receive samples of soil from infected and uninfected localities.

The distribution of snails in relation to soil reaction is similar to that of plants, and it may be added that there is a widespread belief in the west of Ireland that liver fluke disease is caused by eating a certain plant found in fields where the disease has been known to occur. The Gaelic name of the plant was mentioned to one of us, but, unfortunately, it has been forgotten. The distribution of the plant may serve as a guide to the distribution of the snails in question.

Amber and the Dammar of Living Bees.

IN the issue of NATURE for June 3, 1922 (vol. 109, p. 713), a letter is published from Prof. T. D. A. Cockerell, of the University of Colorado, on "Fossils in Burmese Amber." This refers mainly to amber obtained from the amber mines in the Hukong Valley, which I visited in February 1921. In that letter Prof. Cockerell, after investigating the insects preserved in specimens of the amber, agrees with me in placing the age of the amber-bearing beds as the earlier part of the middle Eocene, there being no doubt that the Nummulites found by me are actually *Nummulites biaritzensis* d'Arch.

In the second part of his letter, however, Prof. Cockerell introduces a new problem. In addition to the specimens from the Hukong Valley amber mines, he mentions a number of beads of extremely pale and pellucid amber which he afterwards received from Mr. R. C. J. Swinhoe, of Mandalay. These contained well-preserved insects all different from those identified in the amber from the Hukong Valley mines. Mr. Swinhoe was uncertain whether these beads were Burmese amber or whether they had been imported from China. Prof. Cockerell, after

identifying the included insects in this pale amber, came to the conclusion "that this light amber (or copal) is of very recent origin, not earlier than Pleistocene, and contains a fauna which doubtless consists mainly (at least) of species still living." The point of great interest to me is that among these representatives of still living species he found "a small bee which seems not to differ at all from the common living *Trigona læviceps* Smith."

Now *Trigona læviceps*, or, as it is sometimes called, *Melipona læviceps*, is the actual, or at least chief, source of the common resinous substance known as Dammar (Burmese—Pwé-nyet). These bees build in hollows within trees, crevices among rocks, etc., and line the interior surfaces of their nests with a massive resinous substance. This resinous substance is the common Dammar of the Burmese bazaars, and is used largely by the Burmese for the caulking of boats. Hooper (*Rep. Labor. Ind. Mus.*, 1904–5, 23-4) reports on two samples examined by him. It seems to be the general opinion that it is largely constructed by the bees from the oil and resin of Dipterocarpus.

It seems to me, therefore, that the light amber beads examined by Prof. Cockerell may quite likely be fossil Dammar, or in other words, Dammar deposited in crevices and holes in the earth or rocks by Melipona, which has afterwards been buried up and entombed and fossilised. The inclusion of a specimen of the actual bee in this fossil Dammar would be not only possible but highly probable if such is the case.

Although I do not know the place from which the pale Chinese amber comes, I offer the above suggestion as to its origin; and from what I saw of the actual occurrence of the Burmese amber in the Hukong Valley amber mines it seems to me not unlikely that some such method may be the explanation of its origin also, though in this case one would not expect the depositing insect to be the same species as that depositing Dammar at the present day.

Modern Psilotaceæ and Archaic Terrestrial Plants.

WITH the establishment of an early Devonian group of vascular cryptogams showing fundamental resemblances with the modern Psilotaceæ, the controversy over the essentially primitive or reduced nature of the latter family may be said to be closed. In spite of important points of difference, the resemblances appear to suffice to link the Psilotaceæ with the most archaic types of terrestrial plants of which the structure is known at all adequately. The object of the present note is to record another piece of evidence pointing in the same direction.

As Kidston and Lang say, "In its anatomy Asteroxylon is most closely comparable with the Psilotaceæ and with Lycopodium" ("Old Red Sandstone Plants," etc., Part III., 1920, p. 667). So far as the leafy shoot is concerned, however, the hollow stele of the Psilotaceæ, as generally described, does not readily fall into line with that of Asteroxylon or Lycopodium, in which the centre is occupied by a more or less compact mass of cauline xylem. It is therefore of some interest to note that one or more cauline strands devoid of protoxylem are normally present in the pith of *Tmesipteris Vieillardi* Dang., an erect terrestrial form said to be endemic in New Caledonia. The medullary strands generally arise from the ring of peripheral strands in the transitional region between the rhizome and aerial shoot, and when traced distally as a rule end blindly in the pith, although they sometimes merge into the peripheral strands. They show a good deal of variation in the degree of their development, generally not extending very far up into the leafy shoot, but their presence is a normal feature of the anatomy.

In this respect, therefore, *Tm. Vieillardi* facilitates the comparison of the Psilotaceæ with the Devonian genus Asteroxylon, and also serves to strengthen their lycopod affinity, already established on other grounds. In a paper read before the Cambridge Philosophical Society (see NATURE, June 13, 1918, vol. 101, p. 299) I directed attention to this and other features, in view of which I regarded *Tm. Vieillardi* as the most primitive member of the Psilotaceæ; but the discovery of Asteroxylon adds point to the conclusion there arrived at. It is natural to regard the poorly developed and variable medullary xylem of *Tm. Vieillardi* as a stage in the disintegration of a once continuous and solid cylinder of cauline xylem extending throughout the length of the axis; the hollow steles of *Tm. tannensis* and of Psilotum would thus form the next stage in the reduction. This reduction within the group, however, need not affect the essentially primitive nature of the Psilotaceæ as a whole.

I must add that medullary xylem had previously been recorded in Tmesipteris on two occasions: (i.) by C. E. Bertrand, 1885, "Recherches sur les Tmésiptéridées," p. 248, Fig. 215 (A); and (ii.) by P. A. Dangeard, *Le Botaniste*, 1890–91, p. 17, Pl. XI. Fig. 1. But the nature of the material at their disposal (herbarium specimens) appears to have precluded a detailed investigation by the French authors; they make only a passing reference to the feature in question, apparently considered by them to be only a rare occurrence.

Action of Cutting Tools.

IT is true, as Prof. Andrade points out in NATURE of December 30 (vol. 110, p. 876), that I am "not altogether familiar with the work that has already been done on the subject": indeed it is obvious. And after glancing through the 82 pages of bibliography at the end of Prof. E. C. Bingham's "Fluidity and Plasticity," I feel certain that I shall remain in this state. Tresca's Memoirs, however, are very well known among engineers, and they have been quoted and digested by several writers of engineering text-books and papers, but it is doubtful if the practical use of cutting tools has been much influenced by Tresca's work, beautiful and interesting though it is.

The important problem which faces the user of cutting tools is the preservation of the cutting edge under heavy loads, and while Taylor's work is the outstanding contribution on the matter, Mr. Mallock's explanation of the influence of friction on the upper surface of the tool is invaluable to the machinist. The study of the shaving, while perhaps uninteresting to the physicist, is vitally important to the engineer, for, on one hand, the machinist watches the behaviour of the tool very much in the shaving, and, on the other, the plastic flow on the back of the shaving, which produces flat-backed shavings from round-nosed tools, is probably a principal cause of the undesirable heating of the tool, and an important factor in the frictional phenomena involved.

Natural Resistance and the Study of Normal Defence Mechanisms.[1]

By Prof. J. C. G. LEDINGHAM, C.M.G., F.R.S.

CERTAIN aspects of immunity have long baffled the experimental pathologist and are certain to receive in the future more adequate consideration when the fundamentals of the science of immunity, like those of all experimental sciences, come to be relaid.

The phenomena to which I would direct attention come in the category of what is known as natural immunity or natural resistance—a subject vast and many sided—and I would propose to consider simply what amount of light has been thrown on the elucidation of certain well-known instances of natural immunity to bacterial infection, by the study of the bactericidal functions of body cells and fluids. The infection I would choose for illustrative purposes is that of anthrax, largely because it has been in connexion with the peculiar and fascinating divergencies of susceptibility exhibited by animal species towards this infection, that defence mechanisms have been tested with a view of their elucidation.

When one considers the enormous output of literature on immunity which, since the beginning of the century, has followed regularly the discovery of some new defence mechanism, one has reason to feel that some sufficient explanation might have been vouchsafed us for the existence of these peculiar resistances, but as I hope to show you now, there is no subject in immunity which has been so persistently and yet so inadequately explored. The discovery of a new immunity mechanism has led in the first instance, as a rule, to its intensive exploitation for diagnostic or therapeutic purposes, and rightly so in the main. Some mechanisms have lent themselves more readily than others to such exploitation. Many again have failed to attract anything but a passing fancy and they have been promptly forgotten or ignored, while the great flood of freshly gathered facts and fictions has continued to roll on uninterrupted. And yet if it be true, as I believe, that knowledge is best grasped in its historical setting, then surely these half-forgotten theses must claim the attention of the serious investigator. With the colossal mass of literature on pathology, bacteriology, and immunity on our shelves, it is no easy task to comply with the historical method, but I maintain that the ambition should ever be to build truly on the historical past so that when the time comes for synthesis the old bricks may simply require relaying. The real expert must aim at being a man of vision with a working knowledge of and a pride in a glorious historical accomplishment. A mastery of technique is often, in my opinion, of much less relative value.

Natural immunity remains a dark corner in our edifice. Immunology as an essentially experimental science has undoubtedly gained its chief triumphs in the domain of acquired immunity. It has sought with marked success not only to imitate the immunity that is seen to follow successful combat with the actual disease naturally contracted, but also to transfer the chief bearer of that immunity from the immune subject, be it recovered human or immunised horse, to the acute case. In some notable instances we seem to know with certainty what we are doing in so acting, that, for example, the passive fluid injected represents simply so many units of an accurately titrated substance suspended, we shall say, in a vehicle of serum. So far as we are able to judge experimentally, the vehicle itself might be indifferent. In other cases in which the passive transference of immune serum is followed by undoubted success, as, for example, in anthrax, it has so far been impossible to determine precisely what particular principle in the serum so injected is responsible for the success. In other infections again, such as the coccal septicæmias, the success achieved has been but partial and fortuitous. Either the systems of titration on an *in vitro* basis have been unsatisfactory or, when biological titration has been partially possible, the existing great variety of coccal types both in man and animals and their contrary affinities for various animal species will doubtless for long militate against the elaboration of any rational and stereotyped scheme of serotherapy in these infections. We may learn, however, from our difficulties. We can see that Nature specifically unaided can successfully circumscribe the sphere of operation of a coccal or even an anthrax infection while she may fail to control a general invasion. We note also that Nature not infrequently appears to derive much assistance in the control of infection from the inoculation, for example, of a normal serum or from the inoculation of some type of colloid fluid circumspectly administered. Possibly the not infrequently observed phenomenon of the incompatibility of double infections may be placed in the same category of facts. In any case there would appear to be abundant justification at the present stage of immunological research for the closest study of the normal defence mechanisms.

THE MECHANISMS OF DEFENCE.

It is a strange circumstance that those curious instances of normal resistance which are referred to in all the text-books should rest on such an insecure basis of fact from what one might call the quantitative point of view. They, and the alleged explanatory mechanisms, appeared to fascinate the earlier workers intensely, but it does not appear that the experimental work devoted to their solution can now be regarded as authoritative in the light of present knowledge. It would seem that as each new mechanism of defence was discovered it was immediately tested and generally found to explain the observed resistance to the satisfaction of the discoverer. In what follows I shall illustrate what has happened in the case of anthrax and draw certain inferences as to future lines of progress. Put succinctly, the problem is simply this: Is the mechanism of a certain case of natural resistance capable of full and satisfactory expression in terms of test-tube analysis? Or must other mechanisms than those with which we are familiar be called in to explain the phenomenon?

The mechanisms are not many, and it would appear advisable to summarise them briefly before discussing their application to the problem in question. What contributions to the mechanism of defence were made by the great masters of general pathology and cytology

[1] From the presidential address delivered before the Section of Pathology of the Royal Society of Medicine on October 17.

of the past half-century? I need not discuss the various doctrines and conceptions of inflammation that formed the basis of pathological teaching of possibly most of us, but it is very obvious from even cursory analysis of the works of the great masters that the phenomena of inflammation gradually but surely came to be regarded in the light of natural defence mechanisms. That this was so is abundantly evident at the commencement of the present century, and in illustration I might cite the inaugural address of Marchand, a valued teacher of my own, on assuming the chair of Cohnheim at Leipzig in 1900. The title of his address was "Die natürlichen Schutzmittel des Organismus," and it was an attempt to summarise in the sense of defence mechanisms the various changes produced in the course of the inflammatory process. These changes he regarded as essentially defence mechanisms depending on the reactivity of the local tissues.

On the whole I receive the impression from reading the works of these masters that their methods of work were too local and circumscribed to render the results capable of general applicability to the phenomena of bacterial invasion. They had little conception then of the vast potentialities for defence residing not only in the fluids circulating in the inflamed part but also in the emigrated leucocytes and possibly also in the fixed tissue cells. Since those days the immunologist has had his innings, but I am of opinion that again we shall return to the consideration on ampler lines of local condition and function in the widest sense if we are to understand thoroughly the rationale of natural immunity. Already one sees a tendency towards the combined histological and serological attack on these problems.

I pass to Metchnikoff, whose attempt to extend the sphere of phagocytic action from the physiological to the pathological field, and to read into it the idea of a protective mechanism with an application to all higher animals possessing circulating amœboid elements, constituted the first large-scale conception calculated to raise the lore of inflammation from one of purely local to one of the most general application. It was, in fact, the commencement of immunity as a general science. To him the leucocyte came to be endowed with particular qualities and properties according to the reactivity of the host. It was, moreover, the source *par excellence* of any and all bactericidal substances that might be present in cell-free fluids of the body. The constant polemics into which his rigid adherence to the conception of the all-sufficiency of the phagocyte led him are now matters of history, but it has to be remembered that these very polemics with the rising school of humoralists led by Nuttall, Buchner, and a host of others, gave the stimulus to uncounted researches on the properties and sources of growth-inhibitory and bactericidal bodies in tissues and fluids. Metchnikoff sought to retrieve the position of the phagocyte by many ingeniously contrived experiments, but it was obvious that opinion was definitely ranged alongside the newer humoral ideas, while the ultimate source of the alexin and the intermediary body or *substance sensibilisatrice*, the co-operative action of which with a thermolabile alexin was later demonstrated, were left more or less open questions. The final demonstration by Denys and Leclef, Mennes, and others, showing the dependence of phagocytic action in immune serum on the presence of a *substance sensibilisatrice*, and the extension of the principle to normal serum by Wright and Douglas, constituted a reasonable enough compromise between the opposing views. We know, however, that absolutely independent phagocytic action cannot be excluded as a defence factor, especially when organisms of low virulence are in question, and researches on spontaneous phagocytosis have demonstrated that in a given collection of leucocytes exposed to organisms some individuals undoubtedly appear to possess much higher phagocytic powers than others. We have not reached the end of this particular problem.

After the phagocyte came the alexin of the cell-free fluids. The complex nature of the normal alexin and its presence both in plasma and in cell-free serum are now fairly generally accepted facts. It should be noted, however, that the complex nature of the normal alexin is much more difficult to demonstrate than that of the so-called bacteriolysin in immune serum, and, as we shall see, there is now evidence that certain normal sera possess considerable bactericidal and growth-inhibitory effects which are not destroyed by the usual inactivation temperatures. In fact, the test-organism in all these matters is of prime importance. Here it is sufficient to note that the normal alexin can kill or dissolve certain organisms while others are unaffected or at most suffer growth inhibition.

I pass to the leukins or the bactericidal substances present in extracts of leucocytes. The study of these arose largely out of the views expressed by Buchner and Metchnikoff that the source of the alexin might possibly be found in such. The chief work on this defence mechanism, which has not attracted perhaps the attention it deserves, has been that of Hahn, Schattenfroh, Petterson, Kling, Manwaring, Schneider, and Petrie. I would note simply that these extracts do not lose their power of killing certain test organisms after heating, say, at 60° F. They can resist very much higher temperatures, even up to 80° F. The constitution of these leukins or endolysins is still uncertain. Some have attempted to show that they possess complementing powers in the presence of inactivated sera, but others have entirely failed to confirm such action. Petterson would say that these extracts contain both an alcohol-soluble and an alcohol-insoluble fraction, and that the one can inhibit the action of the other. These effects, however, are almost certainly to be reckoned in the category of inhibition phenomena explicable on colloidal principles. The chief interest of the leukins lies in the effects they produce on different groups of organisms, and in the similarity of such effects to those produced by very analogous extracts prepared from tissues, which were demonstrated twenty years ago by Conradi, Korschun and Morgenroth, Tarassewitsch, and others. These leukins have, as a rule, been tested against organisms of the typhoid-coli group and organisms of the subtilis group, to which anthrax belongs.

Curious differences have been shown by extracts of leucocytes of various animal species in their action on bacterial types. Thus guinea-pig leucocytic extracts are said to possess little or no bactericidal action on *B. typhosus*, while those from the rabbit are distinctly potent. Petrie, however, using extracts prepared from

leucocytes triturated at a temperature of liquid air, failed to demonstrate bactericidal bodies for *B. typhosus* in rabbit leucocytes. The leucocytic extracts of the hen have, according to Schneider, no action on *B. typhosus*, but a very considerable action on *B. anthracis*. On the other hand, the serum of the hen can kill *B. typhosus*, but has little action on *B. anthracis*, so that it would seem that absence of bactericidal property in the extract of a cell might be compensated by its presence in the surrounding fluid, and *vice versa*. The study of bactericidal bodies in tissue extracts and body secretions is again being actively pursued in connexion with bacteriophage problems. In the so-called bacteriophage, from whatever source it may be obtained, there is exhibited the same thermostability and *the same limitation of action to certain bacterial groups*. Rapidity of action of these leucocytic extracts on organisms of the subtilis group and slowness of action on organisms like *B. typhosus*, with subsequent over-growth of presumably resistant organisms, are features which recall those noted in investigations connected with the bacteriophage and with the bactericidal bodies present in egg-white as demonstrated by Rettger and Fleming.

I may close this subject by noting the existence of the thermostable bactericidal body in rat serum. This body has been carefully tested by Pirenne against organisms of the subtilis group, and also organisms like *B. coli* and *B. pyocyaneus*. Plating experiments have shown that organisms like *B. mycoides*, *B. megatherium*, *B. subtilis* are rapidly killed off, while *B. proteus*, *B. coli*, and *B. pyocyaneus* multiply freely. The cholera vibrio is also killed off, but this action was found to be due to the ordinary thermolabile alexin in the rat serum and it disappeared after inactivation of the serum.

There remain only the proteolytic bodies contained in leucocytes, which have been studied by many workers chiefly in connexion with the so-called antitryptic action of serum. We know little or nothing of their action on bacteria, and indeed it would be difficult to separate any such action exhibited from that due to the more generally studied endolysins. I may just mention the alleged existence of bactericidal bodies in platelets, a subject introduced by Gruber and Futaki in 1907, and but little studied since. These authors came to the conclusion that the bactericidal action on anthrax of normal rabbit serum (a highly susceptible animal) depended on substances derived from the platelets. Barreau, who continued this work, found that the serum of the dog (a highly resistant animal to anthrax) had no action on anthrax nor had its platelets. He concluded, however, that the platelet bactericidal bodies or plakins probably did not play much part in natural resistance, as the rat, for example, a resistant animal, was rich in plakins, while the rabbit, a susceptible animal, was equally so. It is possible that the recent work on the purely mechanical function of blood platelets in removing suspended organisms by virtue of their adhesive properties may throw a different light on these alleged bactericidal substances in platelets.

Animal Experiments.

The application of these defence mechanisms to the elucidation of natural resistance to anthrax can now be very shortly considered. The resistant animals chiefly studied have been the frog, the fowl (especially the hen and pigeon), the rat, and the dog, but we have no accurate data of a quantitative kind as to the extent of this resistance in most cases. There is no doubt that the frog presents an extraordinary resistance to anthrax infection—a resistance which in the early days was attributed to its low body temperature. Attempts were made to infect frogs kept at 37° C., and in these circumstances the animals readily succumbed. Metchnikoff attributed the deaths in these cases to diminished phagocytic action, whereas in the frog whose temperature was not interfered with, exuberant phagocytosis at the seat of inoculation afforded sufficient explanation of the immunity. The humoralists, however, maintained that the immunity was due to the bactericidal properties of the local lymph (Nuttall, Baumgarten, Petruschky, etc.). Metchnikoff countered this by showing that *B. anthracis* could grow readily in frog plasma. Galli-Valerio favoured the combined action of phagocytosis and bactericidal property of lymph as the most likely explanation. The matter remains quite obscure, and a more recent worker, Ditthorn, simply states that anthrax rods inoculated in any way into frogs show degenerative changes in a few days and lose their contours. The test organisms may, of course, play a decisive rôle in view of the fact that Dieudonné, for example, cultivated a race of anthrax growing abundantly at 12° C., and with it succeeded in killing frogs readily. These experiments require confirmation.

With regard to fowls, the hen and pigeon, and particularly the former, are known to possess high resistance, and in the classical experiments of Pasteur and Joubert, in 1878, the immunity was attributed to the high body temperature of the fowl. By immersing the fowl in cold water infection took place. The death in such circumstances has been attributed by later workers to a general lowering of resistance, and not to an inability on the part of *B. anthracis* to grow at the high temperature of the fowl. Metchnikoff maintained that phagocytosis in the normal hen was rapid and complete, and in the cooled hen very poor. Later, Thiltges stated that phagocytosis was not in evidence, and that the immunity was due to the bactericidal action of the plasma, a property which Gengou denied. Thiltges agreed, however, with Metchnikoff in the matter of the pigeon. Bail and Petterson and Schneider ascribe the resistance to the action of the hen leukins, which act very powerfully on *B. anthracis*, while the serum has relatively little action. Donati in a more recent communication ascribes the immunity of the fowl simply to a local invasion of leucocytes, which hinder capsule formation, and by virtue of bactericidal substances secreted by them, and not by phagocytosis, secure the removal of the invaders.

It is notorious that the adult dog can tolerate without inconvenience the inoculation of large quantities of bacilli, and, as one might expect, this immunity has been attributed by Metchnikoff to phagocytosis at the site of inoculation. Hektoen later showed that in the presence of dog serum dog leucocytes readily took up *B. anthracis*. It would appear that the serum of the dog has but little or no anthracidal action as compared, for example, with that of the rabbit, which is, on the

contrary, a fairly highly susceptible animal. While without action on *B. anthracis*, dog serum, according to Petrie, has a powerful action on *B. typhosus*. Hektoen attributes some importance also to the leukins of the dog. Petrie, however, found none.

The rat presents a more interesting problem, though it has to be remembered that there is no absolute immunity in this species. Behring, in 1888, showed that rat serum was anthracidal, while Metchnikoff found that the main defence was the phagocytic response. The thermostability of the bactericidal body in rat serum, as shown by Pirenne and Horton, is a most interesting feature. It acts equally well at 18° C. as at 0° C., and remains active for fairly long periods in the cold.

Summary.

To summarise, it must be confessed that the curiously contradictory and yet perhaps genuinely reasonable explanatory theses give us very little that is solid to grasp. No one example of normal immunity has yet been investigated as a complete problem. Partial mechanisms only have been studied. It might be concluded from the above that dogs are immune because dogs are dogs, and so for rats, fowls, and frogs, but that would not be quite the impression I should like to make. If a certain animal is immune to a particular experimental infection, such as anthrax, one ought to be able to explain fully what local phenomena have occurred to prevent a general invasion by the organism. To do so effectively must involve the testing of each possible mechanism separately and in conjunction, and it must involve a return to the cytological study of the changes which the invading organism undergoes *in situ*. The problem must be attacked not only by methods which derive their authority from long experience with the bactericidal properties of cells and fluids, but also by methods which reflect the trend of present-day studies on general metabolism both of parasite and host. With regard to the former much has been made of the capsule, but the data on the point are contradictory. In every set of experiments strict attention must be paid to the maintenance of virulence. It may, indeed, be found that by experimental selection a test organism which has once proved virulent for one individual of a resistant species may prove equally so for all individuals of the species. Strains of *B. anthracis* have been thus selected which are alleged to have killed fowls, rats, and frogs, but the experiments lack confirmation.

Another important aspect of the subject which has recently been brought to the forefront by Besredka relates to the site of inoculation of the test organism. In the course of his researches on the production of immunity by vaccinating that portion only of the body which is most susceptible, Besredka has turned his attention to anthrax infection in the guinea-pig, an animal notoriously difficult to protect by any method of vaccination. He shows experimentally what, by the way, had been amply demonstrated twenty years ago by Noetzel, that animals like the rabbit and guinea-pig can tolerate easily doses of virulent anthrax if introduced directly into the circulation or into the peritoneal cavity without contaminating the cutaneous tissues. This can be avoided by a special and careful technique. According to Besredka the skin of the guinea-pig is the only susceptible portion of the guinea-pig's anatomy, and if it had no skin it would be a highly refractory animal instead of being, as it is, one of the most susceptible. He further demonstrated the possibility of securing solid immunity to anthrax, by whatever route inoculated, by vaccination of the skin with the attenuated Pasteurian vaccines. I do not wholly accept much of the evidence adduced so far in support of the conception of partial or local immunities or susceptibilities, but I believe the matter is worth the fullest investigation. In any case it is obvious that future work on natural resistance must take count of the possibility of very diverse immunities or susceptibilities apparently combined in one immune whole.

I have dealt with species resistance solely, but it has to be remembered that there are racial variations of resistance within the species. For this reason the study of the mechanism of normal immunity will doubtless demand the services of the geneticist, who will be responsible for securing pedigreed stock for experimental purposes. This is no fanciful suggestion. In connexion with these most promising developments in experimental epidemiology which are being carried out in this country and in America the services of the geneticist must be invaluable. The dietetic factor, too, may prove of supreme importance in experiments on natural resistance, and there is already a body of evidence pointing in this direction. It is possible also that we may learn from comparative observations on the rationale of natural immunity in plants to fungal infections. In a recent address by Blackman some of these mechanisms reveal extraordinarily interesting relationships between the attacking fungus and the cells of the immune host.

Helium in the United States.

By Dr. Richard B. Moore, Chief Chemist, U.S. Bureau of Mines.

ONE of the projects started in the United States during the war and since continued, is the extraction of helium from natural gas for use in balloons and dirigibles. In 1907, Cady and McFarland published a report on the presence of helium in a number of natural gases, mainly from Kansas, U.S.A. Some of the samples tested ran as high as 1½ per cent. helium by volume, although the majority of them were considerably below this figure.

Early in 1915 the present writer received a letter from Sir William Ramsay, written under date of February 28. In that letter it was stated that the British Government was interested in new sources of helium other than the atmosphere, in the hope that a sufficient amount could be obtained for use in dirigibles. It was only during my recent visit to England last summer that I learned of Sir Richard Threlfall's intimate connexion with the origin of this demand for a supply of helium by the British Government.

American Government officials heard no more of the

project until after the United States entered the war. A few days after that event, I suggested at the meeting of the American Chemical Society in Kansas City that helium could be, and should be, extracted from natural gas, and the project was afterwards taken to the U.S. Army by Col. G. A. Burrell and myself. Col. Chas. De F. Chandler in charge of the lighter-than-air branch of the Air Service, was immediately interested. The Army and Navy jointly asked the Bureau of Mines to undertake the experimental development of the project, and three plants were built in Texas in connexion with the supply of natural gas derived from the Petrolia, Texas field, used in the cities of Fort Worth and Dallas. Two of these plants were situated at Fort Worth (Fig. 1), and one at Petrolia. The plants at Fort Worth used the Linde and Claude systems respectively. The plant at Petrolia was equipped with the new Jefferies-Norton system of refrigeration.

FIG. 1.—Helium production plant, Fort Worth, Texas, operating at the present time.

During the preliminary stages of the work, Col. Burrell acted for the Bureau of Mines, but shortly afterwards I was assigned by the director of the Bureau to take general charge of the three plants. Others who were connected with the work in the early stages were Dr. Van H. Manning, director of the Bureau of Mines, Dr. F. G. Cottrell, assistant director, and Commanders A. K. Atkins and H. T. Dyer, and Mr. G.

FIG. 2.—Experimental plant No. 1 (Linde system) built and used during the war. Inside a compressor building.

O. Carter, of the U.S. Navy. It was not known at that time that the British Government, through Prof. J. C. McLennan, of the University of Toronto, was carrying out experimental work with the same object in view in Canada.

The U.S. Government had the active co-operation of the Linde Company, the Air Reduction Company, and the Jefferies-Norton Company, and the engineers of the first two companies actually operated their plants. Whatever success was achieved in the commercial production of helium was to a very considerable extent due to the ability of the engineers of the companies mentioned.

Plant No. 1 (Fig. 2), using the Linde process, commenced to work on March 6, 1918, and made its first helium on April 8, 1918, when some gas analysing 27 per cent. helium was obtained. This purity was increased after a few months until in the early part of July a grade of above 70 per cent. was obtained, and in September the plant was operating very consistently, producing an average of from 4000 to 6000 cubic feet of 70 per cent. helium during each operating day. It was necessary to re-process the gas in order to raise this purity to more than 90 per cent.

Plant No. 2, using the Claude system, began to operate on May 1, 1918, and very quickly obtained some helium. On May 13 some gas of a grade between 60 and 70 per cent. helium was produced. The operations of Plant 2, however, were not as a whole so successful as those of Plant 1.

Plant No. 3, using the Jefferies-Norton process, started operations in the late fall of 1918. It was hoped that this plant would show some economies which could not be hoped for from the other two more or less standardised processes. Whereas helium was produced at various times by Plant No. 3, it was never able to produce helium steadily or consistently, and was finally permanently shut down during July 1921.

FIG. 3.—Compressors for experimental work in Cryogenic Laboratory, U.S. Bureau of Mines.

The Linde plant showed the most rapid progress, and it was decided in the fall of 1918 to build a large production plant using the Linde process. This plant was completed in the spring of 1920, and operated for a few months during that year. Most of the time, however, was spent on testing out the equipment. About two million cubic feet of helium averaging 94 to 95 per cent. was produced, and this, with the helium obtained during the experimental work with the smaller plants, gave a total production up to this year of 2,300,000 cubic feet. Congress has furnished a fairly satisfactory sum for operations during the present fiscal year, July 1, 1922 to June 30, 1923, and the plant is now producing about 15,000 cubic feet of 93 to 95 per cent. helium per day.

Some small changes have to be made, and after these have been installed, it is expected that this production will be considerably increased. When all the units are operating efficiently, the plant will probably have a capacity of from 35,000 to 40,000 cubic feet per day.

An important part of the work has been the investigation of the natural gas supplies of the United States for their helium content. This work was originally started during the war, and Mr. G. S. Rogers, of the U.S. Geological Survey, was transferred to the Bureau of Mines to carry on the work. A preliminary report was published by the Survey in 1921 (U.S. Geol. Sur. Professional Paper 121, by G. Sherburne Rogers).

Since 1919 the present writer has supervised the field work along with other helium activities; and the Bureau maintained a full force and laboratory for this particular purpose for nearly two years. Every gas field in the United States has been sampled, and at the present time undoubtedly more than five hundred million cubic feet of helium is going to waste annually in connexion with the natural gas of the United States. A considerable proportion of this is widely scattered in gas-wells that have a small helium content, of only 0·1-0·2 per cent., but a considerable amount of it is concentrated in large fields which have an average of more than 0·5 per cent. helium in the gas, and some of the wells go above 1·0 per cent. and even 1½ per cent. In general, the helium belt extends from Texas through Oklahoma, south-eastern Kansas, southern Illinois, and from there through Ohio into Pennsylvania and New York. There is also helium-bearing gas in Indiana, Kentucky, and West Virginia. The belt seems to go from south-west to north-east, generally speaking, the richest gas being in Texas, Oklahoma, and Kansas.

Though helium is being produced successfully commercially, we are not satisfied with the present development or costs. A considerable amount of research work is being carried out, therefore, with the main object of getting greater efficiency and reduction in cost.

The low-temperature laboratory (Fig. 3) is attached to the Bureau of Mines in Washington, with a force of about fifteen chemists, physicists, engineers, and mechanics. A thoroughly adequate equipment is available. A good deal of fundamental research work is being carried on and applied to the commercial production of helium. A consulting board of engineers consists of Mr. M. H. Roberts, Prof. W. L. De Baufre, and Dr. R. C. Tolman. This board is giving efficient and valuable help on plant design. It is assisted by Mr. J. W. Davis of the Bureau of Mines, and other members of the technical force. Mr. C. W. Seibel, Dr. A. G. Loomis, Dr. Leo Finkelstein, and Mr. W. V. Cullison have been with the work for a considerable time, and are giving valuable service.

Two repurification plants are being constructed by the Bureau of Mines for the U.S. Army. The object of these plants is to repurify the helium after it has been used in a balloon or dirigible. One of these plants is situated at Langley (Aviation) Field, Va., and uses the ordinary combination of low temperature and high pressure in order to step up the purity of the gas. Dr. H. N. Davis has acted in a consulting capacity for this plant. The present writer felt from the early start of the project that the use of charcoal at low temperatures would be of value, and, therefore, a considerable amount of research work has been carried out, and has culminated in a repurification plant in two railroad cars. One of these cars is equipped with a self-contained power unit, and the other contains the necessary compressors, refrigeration outfit, and charcoal purifiers. By means of charcoal, a purity of practically 100 per cent. can be obtained. Both these plants will be ready for operation within a very short time.

At the present time the Helium Board which handles the whole project consists of Col. I. F. Fravel, Commander S. M. Kraus, and myself. Others beside those already mentioned in this statement who have been intimately connected with the work are Major O. Westover, Major P. E. Van Nostrand, and Lieut. R. S. Olmsted, of the U.S. Army.

Current Topics and Events.

THE following presidents and recorders of the various sections of the British Association have been appointed for the Liverpool meeting to be held in September next under the presidency of Sir Ernest Rutherford:—*Section A* (*Mathematical and Physical Science*): Prof. J. C. McLennan; Prof. A. O. Rankine, Imperial College of Science and Technology, S.W.7. *Section B* (*Chemistry*): Prof. F. G. Donnan; Prof. C. H. Desch, The University, Sheffield. *Section C* (*Geology*): Dr. Gertrude Elles; Dr. A. R. Dwerryhouse, Toots, Darell Road, Caversham, Reading. *Section D* (*Zoology*): Prof. J. H. Ashworth; Prof. R. D. Laurie, University College, Aberystwyth. *Section E* (*Geography*): Dr. Vaughan Cornish; Dr. R. N. Rudmose Brown, The University, Sheffield. *Section F* (*Economics*): Sir W. H. Beveridge; Prof. H. M. Hallsworth, Armstrong College, Newcastle-on-Tyne. *Section G* (*Engineering*): Sir H. Fowler; Prof. G. W. O. Howe, The University, Glasgow. *Section H* (*Anthropology*): Mr. P. E. Newberry; Mr. E. N. Fallaize, Vinchelez, Chase Court Gardens, Enfield, Middlesex. *Section I* (*Physiology*): Prof. G. H. F. Nuttall; Prof. C. Lovatt Evans, Physiological Laboratory, St. Bartholomew's Medical College, E.C.1. *Section J* (*Psychology*): Mr. C. Burt; Recorder not yet appointed. *Section K* (*Botany*): Mr. A. G. Tansley; Mr. F. T. Brooks, 31 Tenison Avenue, Cambridge. *Section L* (*Educational Science*): Prof. T. P. Nunn; Mr. D. Berridge, The College, Malvern. *Section M* (*Agriculture*): Dr. C. Crowther; Mr. C. G. T. Morison, School of Rural Economy, Oxford.

THE Buys Ballot medal founded in 1888 in commemoration of the work of C. H. D. Buys Ballot, the famous meteorologist of the Netherlands, to be awarded by the Royal Academy of Science at Amsterdam first in 1893, and afterwards every tenth year, to the person who is judged to have made the most valuable contributions to the science of meteorology, is to be given this year to Sir Napier Shaw, professor of meteorology in the Royal College of Science, late

director of the Meteorological Office, for contributions to all branches of the science, and specially for his work as president of the International Meteorological Committee. The previous awards were: 1893, Dr. Julius Hann, of Vienna; 1903, Dr. R. Assmann and Dr. A. Berson, of Berlin, jointly; 1913, Dr. H. Hergesell, of Strasbourg.

MR. E. A. REEVES, map curator of the Royal Geographical Society and director of the society's School of Surveying, has been awarded the Cullum Gold Medal for 1922 of the American Geographical Society. The inscription on the reverse side of the medal reads as follows:—"Edward A. Reeves, 1922. In honour of his substantial achievements in geographical surveying. By devising and improving instruments and methods he created new standards in the field of scientific exploration." Mr. Reeves has now been in charge of the Royal Geographical Society's courses of instruction in map construction and surveying for twenty years, and during that period almost every British explorer, as well as many from other countries, have had the advantage of his practical knowledge and precise methods. One of these pupils was Dr. Hamilton Rice, vice-president of the American Geographical Society, who worked through the course some years ago and obtained the diploma. This society is starting a survey school for travellers and explorers under Dr. Rice's direction, and the future instructor, Mr. Weld Arnold, late Austin teaching fellow in astronomy at Harvard University, is now passing through the Royal Geographical Society's course. The award to Mr. Reeves is no doubt in some measure a mark of recognition of his valuable services in connexion with these developments.

The annual council meeting of the National Union of Scientific Workers was held at the Caxton Hall, Westminster, on January 13. Dr. A. A. Griffith, who presided, gave an address on "The Support and Utilisation of Science," in which he stated that it was the general opinion of men of science that the support of science in Great Britain is quite inadequate considering the needs of the country. He regarded it as absurd that science, the greatest and most permanently valuable of all the learned professions, is also the worst paid, and outlined a general policy for adoption by the Union which aims at remedying this condition of affairs. Scientific workers themselves must be held largely to blame for their present unenviable position, and would only prove their value to the community when they undertook a greater share of responsibility in the control of the product of their labours. Unity among men of science is the first essential of success, he declared. Dame Helen Gwynne-Vaughan was unanimously elected president for the ensuing year, and the following were elected members of the executive committee: Profs. J. McLean Thompson and H. Levy; Drs. H. Jeffreys, G. Senter, J. H. Vincent; Messrs. W. L. Baillie, E. G. Bilham, F. T. Brooks, L. D. Goldsmith, R. McKinnon-Wood, S. W. Melsom, and H. V. Taylor.

AT a large gathering of Whitworth scholars and exhibitioners held at the Institution of Mechanical Engineers on Friday, January 12, the Whitworth Society came into being. The president of the Institution—Dr. Hele-Shaw, himself an old Whitworth scholar—welcomed those present, and took the chair. There had been great difficulty in getting into touch with Whitworth men, but more than three hundred had indicated their desire to support a society if formed, and about 120 were present at the meeting. The new society will enable old scholars, exhibitioners and the prizemen who will come into being under the new scheme of award to keep in touch with one another. It has no connexion with any existing institutions, although there is no doubt that these will welcome its advent. Dr. Hele-Shaw was elected president of the new society, and a provisional committee was appointed. It will assist greatly if any such who have not already received communications would send their names and addresses to the secretary, the Whitworth Society, Institution of Mechanical Engineers, Storey's Gate, London, S.W.1. It is proposed to have an annual social function on the anniversary of Sir Joseph Whitworth's birth—December 21—and the committee has been asked to organise if possible a similar function to take place within the next three months. An interesting feature of the meeting was the number of men, many occupying prominent positions in their professions, who bore testimony in speech and in letters to the value which Sir Joseph Whitworth's generosity had been to them in their educational training in engineering.

ACCORDING to the *Journal officiel de la République Française*, the "Croix de chevalier du Mérite Agricole" has recently been awarded by the French Ministry of Agriculture to 287 agriculturists, both men and women, whose families have dwelt on the same agricultural holding for more than one hundred years and who are themselves still carrying on the working ot the land. Exceptional interest attaches to two cases on account of the long association of the families of the recipients with the property. M. André Dupont, of Lacoux (Ain), traces his descent back for eight hundred and twenty-two years on the same holding; he himself has devoted his life to practical agriculture, and for the last thirty-five years has done much to extend agricultural co-operation. M. Pierre Lascassies-Poublan, of Lucgarrier (Basses-Pyrénées), is also an excellent farmer and is president of various co-operative societies connected with agriculture. In this case the family has been uninterruptedly associated with the same land over a period of eight hundred and eighty-nine years.

THE Royal Scottish Society of Arts has awarded the following prizes for communications read or reported on during the session 1921–22: Keith prizes to Principal A. P. Laurie for his paper on "The 'Pier Method' of Building Brick Walls," and to Dr. Henry Briggs for his paper on "A New Mine Rescue Apparatus"; Makdougall-Brisbane medals to Andrew H. Baird for his paper on "The Universal Bosshead-Clamp," and to Dr. Dawson Turner and

D. M. R. Crombie for their paper on "An Investigation of the Ionised Atmosphere around Flames by means of an Electrified Pith Ball"; and a Hepburn medal to Basil A. Pilkington for his paper on "A Readily-Destructible Material suitable for the Conveyance of Confidential Communications."

IN connexion with the work of the School of Meteorology of the Royal College of Science, Sir Napier Shaw, professor of meteorology at the College, will give a course of ten lectures on "Forecasting Weather," at the Meteorological Office, South Kensington, during the current term. The lectures are on Fridays at 3 P.M., beginning on Friday, January 19. Admission is free by ticket to be obtained from the Registrar of the Imperial College of Science, South Kensington, S.W.7.

OWING to the exceptional demand for tickets for his lecture on January 23, Prof. W. M. Flinders Petrie has consented to repeat the lecture on "Royal Burials in Egypt" on Saturday, February 3, at 2.30 P.M., at University College, London. The lecture, which will be illustrated by lantern slides, will have special reference to the recent excavations in Egypt. The proceeds will be devoted to the St. Christopher's Working Boys' Club, which is connected with the Union Society and Women's Union of the College. A leaflet containing full particulars as to the prices of the tickets can be obtained by sending a stamped addressed envelope to Dr. Walter Seton, University College, London (Gower Street, W.C.1.).

THE council of the Geological Society has this year made the following awards:—Wollaston Medal, Mr. W. Whitaker; Murchison Medal, Dr. J. Joly; Lyell Medal, Mr. G. F. Dollfus; Bigsby Medal, Mr. E. B. Bailey; Wollaston Fund, Mr. H. H. Read; Murchison Fund, Mr. T. H. Withers; Lyell Fund, Dr. W. T. Gordon and Dr. W. N. Benson.

WHAT is claimed to be the first deliberately organised radio-telephone conversation between Great Britain and the United States is recorded in the *Times* of January 16. In the early hours of the morning of January 15, Mr. H. B. Thayer, president of the American Telephone and Telegraph Company, succeeded in addressing a party of press representatives and others at the New Southgate (Middlesex) works of the Western Electric Company, Limited, from his office at 195 Broadway, New York. Communication was maintained for two hours. The demonstration was carried out by the American Telephone and Telegraph Company and the Radio Corporation of America, which had installed a transmitting apparatus for the purpose at Rocky Mount, Long Island. The transmitter was connected with New York by telephone wires. The power used is stated as "several hundred" kilowatts and the wave-length was approximately 5350 metres. At New Southgate a special receiving set with eight valves was employed, with an indoor frame aerial about six feet square. It is stated that most of the words spoken by Mr. Thayer and others who followed him were heard both by means of head telephones and also by a "loud-speaker" so clearly that it was possible to recognise one of the speakers by his intonation. The success of this experiment in transmitting the spoken word from the New to the Old World is a noteworthy step in the progress of practical radio-telephony.

THE annual general meeting of the Institute of Metals will be held on Wednesday and Thursday, March 7 and 8, at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W.1, commencing at 10.30 A.M. each day. The council is arranging a special ballot on February 22 for the election of members in time for this meeting, and candidates who are elected will enjoy the privileges of membership for the extended period ending June 30, 1924. With the view of developing the membership of the Institute Overseas, the council has recently appointed a British Empire Committee on which the Overseas Dominions are represented by distinguished metallurgists in London possessing an intimate knowledge of Overseas conditions. A local section of the Institute has just been formed in Swansea as a sequel to the autumn meeting of the Institute held there in September last. Thus the Institute now has sections in Birmingham, Newcastle-on-Tyne, London, Sheffield, Glasgow, and Swansea.

A SPECIAL exhibit of epiphytic ferns belonging to the genus Platycerium and some species of the genus Polypodium has been arranged in the Tropical Fern House at the Royal Botanic Gardens, Kew. These ferns live mainly in the air attached to tree trunks, and they have developed either specially modified bases to their leaves—as, for example, *Polypodium Heracleum*, *P. conjugatum*, and *P. Meyenianum*—or special "shield" or "collecting" leaves, as in *P. quercifolium*, *P. Vidgeni*, and *P. rigidulum* var. *Whitei*, which serve to collect the humus and detritus washed down the trunks. In the case of the Stag's Horn Ferns (Platycerium) the collecting leaves are specialised organs which wrap round the tree trunks, and the roots grow out into the pockets so formed. The shield-like base of the frond of *Polypodium Heracleum* remains green, as does also the whole shield-leaf in *Platycerium grande* and *P. Veitchii*, while in *Polypodium quercifolium* etc., *Platycerium alcicorne*, *P. æthiopicum*, and *P. Willinckii*, etc., the shield-leaf turns brown and functions only as a collecting leaf, the frond which remains green and bears the sporangia or reproductive bodies being a separate frond. The Bird's Nest Fern, *Asplenium Nidus*, and other ferns which tend to make pockets with their leaves may be compared with these Polypodiums and Platyceriums, and are also exhibited near them.

USEFUL work is being done by the various trade and technical committees of the British Empire Exhibition to be held at Wembley in 1924. It is to these committees that the executive council and the management committee have delegated the task of organising representative exhibits of the particular

trades with which they are concerned. The larger industries are being organised entirely by their own trade associations, including the British Engineers' Association for mechanical engineering exhibits, the British Electrical and Allied Manufacturers' Association for all electrical exhibits, and the Association of British Chemical Manufacturers; but in the case of many other trades about fifty representative committees have been set up to work in conjunction with the exhibition officials, and they are now holding regular monthly or fortnightly meetings, with the object of inviting exhibitors, individually or in groups, securing the requisite amount of space, and arranging and classifying the exhibits. The committees are getting into communication with all traders in the different trades. Some of the smaller traders, it is thought, may desire to economise by exhibiting in groups. Provision for this will therefore be arranged. Sir Lawrence Weaver, director of the United Kingdom Exhibits Section, is attending the meetings of these committees, in order to explain the nature of the work, and to see that the committees are enlarged, where necessary, to ensure their representative character. He has explained also that the executive committee, desiring to evolve unified schemes of decoration for each section, has obtained the services of a panel of eminent architects who will advise committees in regard to decorative schemes.

THE annual meeting of the Circle of Scientific, Technical, and Trade Journalists was held in the Hall of the Institute of Journalists on January 9, when Sir Richard Gregory was elected chairman in succession to Mr. L. Gaster (32 Victoria Street, London, S.W.1), who has been chairman for the past eight years and has now consented to serve as secretary. In opening a discussion on "Reviews and Reviewers," Sir Richard Gregory referred to the distinctions between the points of view of publisher, author, and editor. The first concern of an editor is, however, the interests of his readers. So many books are received for review by leading journals that it is impossible to find space to notice them all, and a selection has, therefore, to be made. Books may be selected for special notice on account of (1) wide interest of subject, (2) eminence of author, (3) outstanding importance. The most readable review, if written with expert knowledge of the subject, is editorially the most acceptable and probably best directs attention to the book noticed. A mere statement of contents is not a review, though a descriptive synopsis may serve a useful purpose. Readers are not interested in long lists of errors, and it is preferable to send such lists to publishers or authors instead of printing them. Books not selected for special reviews may be dealt with in short notices, but, on account of limitations of space, many can be mentioned only in lists of books received. It was the general opinion of the editors of different types of technical journals who took part in the discussion that while an unsigned review might be subjected to a certain amount of editing, no essential change should be made in a signed review. Custom has sanctioned the principle that a book noticed by a reviewer becomes his property, and the view was expressed that, provided a reasonable period had elapsed since the date of publication, books merely announced might be sold or disposed of in any way.

Our Astronomical Column.

THE DRAYSON PARADOX.—A pamphlet by Mr. A. H. Barley on "The Drayson Problem" shows that this curious paradox has still a considerable vogue. It had its origin solely in the somewhat loose language of certain text-books which described the motion of the pole of the equator as circular, the pole of the ecliptic being in the centre. This description would be correct if only the solar and lunar precessions were concerned, but planetary perturbations cause the plane of the ecliptic (and hence its pole) to shift, thus causing a variation in the radius of the circle. Drayson, without carefully studying the evidence for the shifting ecliptic, asserted that it was really fixed among the stars, and that the centre of the north pole's motion was 6° away from the ecliptic pole, thus bringing about a very large change in the obliquity, which he supposed to be near its minimum at present. It would reach 35° at its maximum, when Drayson considered an Ice-age would occur. Drayson's supporters slur over the fact that all the planetary orbit planes are changing, owing to mutual perturbations, theory and observation being in good agreement. Further, they claim to account for stellar proper motions by their revised precessions, omitting apparently to note that motions due to a mere change in the earth's axis would affect all the stars in the same region of space alike, whereas the actual motions differ from star to star, as can readily be verified from stellar photographs. If the Draysonians would study the full collection of modern observations of sun, planets, and stars, instead of wresting a few isolated observations to suit their preconceived views, they would soon be convinced that their hypothesis is not consistent with the facts, but that the ecliptic is actually shifting through an angle of some 47″ per century.

PARALLAXES OF FIFTY STARS.—The Sproul Observatory has just issued No. 6 of its publications, a continuation of numbers 4 and 5, which contains a third list of trigonometrical parallaxes of 50 stars. The observational work has been spread over the years 1915–1921 and the results were obtained through the efforts of several persons named in the volume. The list includes stars of various types of spectra and magnitudes, the latter ranging from 2·81 to 10·5. This list is very opportune, as the values will assist in the researches now being carried out in the determination of parallaxes by the spectroscopic method.

VARIABLE STAR MAXIMA AND MINIMA FOR 1923.—Variable star observers will find the Harvard College Observatory's Circular No. 241 very useful. Dr. Leon Campbell publishes in it the predicted dates of maxima and minima for variable stars of long period. The dates for 366 variables are inserted in the table. The information is given in the following form: first, six figures which denote the Right Ascension and Declination of the star; next, the name of the star according to the new nomenclature instituted by the International Astronomical Union; and, lastly, the dates of the maxima and minima showing the months and days of the month. Thus, for example, o Ceti or "Mira" with R.A. $2^h\ 14^m$ and Dec. $-3°$ reaches a maximum on April 2 and a minimum on October 23.

Research Items.

KENT'S CAVERN ANTHROPOLOGY AND THE ICE AGE.—In the Journal of the Torquay Natural History Society (vol. iii. No. 2, 1922), Mr. H. J. Lowe gives a full account of the questions connected with the exploration of Kent's Cavern. The first exploration was made by MacEnnery in 1825, but the success attained was due to the labours of W. Pengelly, who spent sixteen years in excavating and recording his discoveries. Probably the greatest service Pengelly did for anthropology was when, with a keen appreciation of the importance of the results already attained, he secured the right to investigate a newly found cavern at Brixham, across the bay from Torquay. The writer, comparing the results of excavation at Kent's Cavern, Brixham, and Tor Bryan caves, with those of a Belgian cavern in about the same latitude, as noted by Schmerling, advances the theory that their floors mark periods of climatic severity that destroyed life so far south, at least, as the latitude in which they occur; and inferentially that they may be regarded as indications of cosmical changes that need to be discovered in order to explain the phenomenal coincidences.

SHRUNK HUMAN HEADS.—The *Lancet* (November 11, 1922) publishes an address, entitled "Spolia Nemoralia: Shrunk Heads, Ear-plugs, and Labrets," delivered by Sir John Bland-Sutton before the Royal Society of Medicine. The art of producing these shrunk heads is found among Indians dwelling in the dense forests bordering the section of the Amazon known as Marañon. The specimens exhibited were collected by the lecturer on a visit to the Amazon, and further information has been acquired by Mr. G. M. Dyott in a recent adventurous journey. As a rule a corpse is flung into the river, but when a man is killed in combat his body is mummified, wrapped in bark, and placed on a stand in the centre of the hut as an object of veneration. After the skull is removed the flesh of the head is stuffed with hot pebbles or hot sand and carefully dried in the sun. When this rude taxidermic process is complete, the flesh shrinks to the size of an orange, preserving the features. It is clear that Amazonian Indians, as well as the natives of East Africa, like surgeons in civilised countries, are familiar with the elastic properties of the human skin.

DISTRIBUTION OF THE BOTULISM ORGANISM.—A good deal of interest was aroused last year over the outbreak of food poisoning at Loch Maree in Scotland, where a number of fatalities followed the eating of some potted meat in which, for the first time in this country, the *Bacillus botulinus* was identified as the causative agent. The last number of the *Journal of Infectious Diseases* (vol. xxxi. No. 2) contains a series of papers from the University of California by Prof. K. F. Meyer and his colleagues on the distribution of this organism. In 624 samples of soil, vegetables, fruit, feeding stuffs, etc., collected in California, the bacillus was found in about 30 per cent., and, contrary to the common assumption, more abundantly in virgin mountain and forest soils than in cultivated places. By serological reactions two types, A and B, may be distinguished, and it is the former that is particularly associated with wild places. Extending their studies more widely, they have found it in earth all over the United States, more abundantly and more generally of type A in the west than the east, in Canada, Belgium, Denmark, Holland, England, Switzerland, China, and Hawaii. The bacillus seems indeed to be a common soil anaerobe; like other bacteria, it has a world-wide distribution, either because it is easily transported or because it is ancient. It is not, like the tetanus bacillus, specially associated with the intestinal tract and with soil contaminated by excreta, but man must very frequently come into contact with it and take it in with food. The conditions under which it will grow in foods and produce enough toxin to cause symptoms in man have not yet been defined, but they must evidently be seldom realised, for botulism is, and always has been, quite a rare disease.

DEVELOPMENT OF SOME ABERRANT CTENOPHORES.—Prof. T. Komai has recently published studies on two aberrant ctenophores—Cœloplana and Gastrodes (Kyoto; 102 pp.). He has had abundant material of three species of Cœloplana which need no longer be considered a zoological rarity, for the author was able to obtain 50 or 60 *C. bocki* creeping, after the fashion of a planarian, on a single colony of Dendronephthya. He gives a careful account of the anatomy and histology, and shows that the pharynx, at first like that of a Cydippe, becomes divided into two parts—a dorsal, which persists as the pharynx of the adult, and a ventral part which spreads out and forms the surface on which the animal creeps. The eggs are kept under the body of the parent, where they develop and finally hatch as cydippiform larvæ with mouth, pharynx, and canal system. After swimming for about a day the larva begins to remain at the bottom and adheres by or glides on the everted external portion of the pharynx. The cilia of the comb-plates degenerate and the animal, which is henceforward incapable of swimming, gradually becomes flattened. Cœloplana is an extremely modified ctenophore adapted to a creeping mode of life, and its resemblance to a planarian is due to convergence. Prof. Komai has obtained 120 examples of Gastrodes, which lives as a parasite in the mantle of Salpa, and has shown that it enters the Salpa as a planula and grows there into a cydippiform ctenophore about 3 mm. in diameter. It is believed that at this stage it is liberated and sheds its eggs.

FIXATION OF NITROGEN BY THE WHEAT PLANT.—Lipman and Taylor announce (*Science*, November 24) that they have proved conclusively that wheat plants can fix nitrogen from the air in amounts up to 21 per cent. of the total nitrogen content of the plant. The publication of the evidence upon which this startling announcement is made will be eagerly awaited by agricultural research workers, modifying as it does much of the theory upon which current practice in the use of nitrogenous fertilisers is based. The classic researches of Lawes and Gilbert in the eighties of last century have long been deemed to have proved conclusively that the Leguminosæ alone of cultivated plants have the faculty of fixing atmospheric nitrogen, a power which they exercise not directly but through the agency of the nodule organisms on their roots. In their preliminary note in *Science*, the authors recall that one of the heresies maintained many years ago by Jamieson was that all green plants have the power of fixing atmospheric nitrogen (Rept. Agr. Res. Assn., Aberdeen, 1905). It is interesting to note that another of the heterodox views held by this veteran worker was that plants have the power of directly absorbing "insoluble" phosphates. The availability of such substances as plant food is no longer in doubt, and, whatever the mechanism of their entry may be, it is now admitted by botanists and soil chemists that many substances insoluble in water can find their way into plant tissues. Jamieson's facts, therefore, appear to have been right in this case also, although his deductions from them may have been unsound.

TEMPERATURE-RADIATION FROM CLOUDS.—The temperature-radiation from clouds at night is discussed by A. Defant in *Geografiska Annaler* (1922 H. 1.). Some of the radiation that leaves the cloud is absorbed during its descent to the measuring instrument, which is placed on the ground. At the same time the intervening clear air sends out its own temperature-radiation, some of which reaches the instrument. By making allowance for these complications, Defant calculates that a uniform stratus cloud radiates from its lower surface with an intensity almost the same as (actually 2½ per cent. greater than) that of a "full" radiator at the temperature of the cloud. His calculation involves the assumption that the only constituent of the clear atmosphere which radiates energy is the water-vapour. He also reduces observations of the nocturnal cooling of the air at various observatories, and finds that:

(the cooling per hour when w tenths of sky are clouded) = (same quantity when sky clear) $(1 - 0{\cdot}76\, w/10)$.

WATER POWER IN INDIA.—The issue of the Journal of the Royal Society of Arts for December 15 contains the report of a meeting at which a paper by Mr. J. W. Meares on "The Development of Water Power in India" was read and discussed. The paper was largely a condensed account of information collected by the Hydro-Electric Survey of India and published *in extenso* in the Triennial Report of last year. Mr. Meares, as Electrical Adviser to the Indian Government, was associated, first with the late Mr. G. T. Barlow, and later with Mr. F. E. Bull, successively Chief Engineers of the Survey, in the preparation of the report, and in the analysis of data for potential hydro-electric development schemes. The salient results of the investigation were as follows. In the year 1921, some 350,000 e.h.p. had been developed, or was in course of realisation. Sites had been examined which gave satisfactory evidence of a further 1½ million e.h.p. continuously throughout the year. Other sites, not fully examined, were reasonably expected to yield a further 1½ million e.h.p. continuously. Finally, there were sites of which little was known but their existence, the capacity of which was speculatively, but cautiously, reckoned at 4 million e.h.p., so that "it is perfectly safe to say that at least 7 million e.h.p. is in sight on the most conservative estimate and on the basis of *absolute* minimum continuous power." In announcing these results, Mr. Meares deplored the fact that he was practically in the position of delivering a funeral oration on the Survey, which was moribund for lack of financial assistance.

AN ELECTRIC MICROSCOPE LAMP.—We have received from Messrs. Ogilvy and Co., 18 Bloomsbury Sq., W.C.1, a new form of electric microscope lamp, specially designed for research work. An opal electric bulb of the half-watt type is enclosed within a cylindrical metal hood which is practically light proof, though well ventilated. The holder of the electric bulb is provided with a push-bar switch. The base of the metal hood is detachable, and a slot cut in it fitting over a clamping screw with milled head ensures replacement in the correct position. The hood runs on an upright pillar supported on a heavy tripod base, which gives complete stability, and can be clamped by screws with milled heads in any position of elevation and inclination. The light passes through a circular window cut in the metal hood; this is provided with an iris diaphragm, by means of which the size of the source of light may be regulated. A small prismatic optical bench is attached to the front of the base of the metal hood; this carries two adjustable supports on saddle stands. On one of these is a condensing system, provided with centring screws and iris diaphragm, which is hinged so that if required it may be swung out of the optic axis. The other support is a holder for a cell or light filters. By these arrangements perfect centration of the light and "critical" illumination are obtainable. The instrument is beautifully finished and fulfils the purpose claimed for it; the price (12*l.* 10*s.*) is reasonable, though we fear beyond the reach of most microscopists.

AN ARC RECTIFIER.—At the meeting of the French Physical Society on June 16, MM. L. Dunoyer and P. Toulon gave an account of their experiments on the passage of current through an alternating electric arc with one of the electrodes cooled by the circulation of water through it. They find that whatever the material of the cooled electrode the current only flows when that electrode is the anode. They explain this result as due to the inability of the cooled electrode when it is the cathode to emit the electrons necessary to carry the current. The same effect is obtained between a third cooled electrode and either of the two electrodes of an ordinary alternating arc into which it is introduced. With this arrangement it has been possible from an alternating arc at 110 volts taking 2·5 amperes to obtain by means of a transformer in circuit applying an average of 95 volts to a cooled third electrode a rectified current of 90 amperes. The rectified arc is stable, but the rectified current is not yet steady enough for many industrial purposes.

THE GAUMONT LOUD-SPEAKING TELEPHONE.—At the meeting of the Paris Academy of Sciences on November 27, M. L. Gaumont gave an account of his new loud-speaking telephone, and an illustrated article on it appears in *La Nature* for December 16. The vibrating part of the instrument consists of a silk cone of angle 90° on which is coiled from base to summit a fine wire of aluminium, through which the telephonic current is sent. The cone is placed between cone-shaped poles of an electromagnet and its base is attached to one pole by a collar. As the vibrating cone possesses no period of its own, its motions reproduce without distortion those of the membrane which produced the current. These motions are communicated to the air around the instrument through holes bored in one of the pole pieces and through a trumpet-shaped mouthpiece. With a silk cone of 5·5 cm. diameter weighing 1 gram it was possible to make an ordinary speaking voice heard throughout a room holding 6000 persons without any distortion of the sounds. By introducing a triode valve in the circuit the apparatus transmitted the sound 300 metres.

LARGE THERMIONIC VALVES.—At the Institution of Electrical Engineers on December 7 there was an interesting exhibition of 10 kilowatt vacuum tubes, which are recent developments of the thermionic rectifying valve described by Prof. Fleming in 1904. The large 10 k.w. tubes are used for radio transmission and are of two types, the rectifier (two electrodes) and the oscillator or amplifier (three electrodes). The tubes have water-cooled anodes consisting of a copper tube which is fused to the glass bulb by means of a special copper-glass seal. When in action the tube is mounted so that the anode is surrounded by a metal joint through which cooling water circulates. In the 10 k.w. tube the filament current is 24 amperes, the filament voltage is 32, and the normal plate voltage is 10,000. The power taken by the tube, including the losses inside the tube, is 15 kilowatts and the output power delivered from the tube is 10 kilowatts. The perfecting of these large valves will have a great influence on the future development of radio-communication.

Belgian Botany: a Record of War Time.

THE Botanical Institute, close to the Botanic Gardens in Brussels, which bears the name of that distinguished Belgian botanist, Léo Errera, has resumed its activities since the war and is again under the guidance of Prof. Jean Massart of the University of Brussels. A large volume, Part 2 of vol. 10 of the collected papers of the Institute, has recently appeared, published in Brussels, with many plates, text-figures, charts, and maps, together with a list of the communications published in the earlier volumes. Most of the papers have previously appeared in scientific journals in France or Belgium, but we note as apparently new contributions a brief note by Henri Micheels, comparing the effect upon seedling germination of the anions Cl and NO_3 and the cations K and Na, a note reporting the presence of calcium thiosulphate in *Achromatium oxaliferum* Schew by Germaine Hannevart, and a continuation of phenological observations by E. Vanderlinden, meteorologist to the Belgian Royal Meteorological Institute, which is lavishly illustrated by charts, and a description of the vegetation succeeding upon the war-time inundations of the Yser and upon the ruins of Nieuport.

Prof. Massart's earlier studies of the vegetation of the Belgian littoral make him the natural chronicler of the intense subsidiary struggle waged among the vegetation of this region and maintained long after the armistice of 1918. Behind the dunes bordering the Belgian coast there lies a long stretch of country, the level of which is intermediate between the level of the high and low tides of the sea. On October 29, 1914, the Belgian engineers opened the locks at high tide and allowed the sea to flow over this portion of their front, thus preventing the farther advance of the German forces, and giving their own heroic troops a well-earned respite. For four long years these inundations remained upon the land, fully maintained in winter by the natural rainfall and humid atmosphere, in the drier season assisted by the regulated influx of the sea controlled by the Belgian engineer service. Prof. Massart, aided by official photographs and maps, gives a vivid account of the effect of these conditions upon the vegetation, and, by further striking photographs of his own, records the rapid recovery of the vegetation of the region since the salt-water invasion finally ceased at the close of the war (Figs. 1 and 2).

FIG. 1.—Raised footpath near Ramscapelle after retreat of floods, May 1919. Only vegetation, tufts of *Phragmites communis* in distance.

FIG. 2.—Same path in September 1920. Some of supports of original planking left, ground covered with *Aster trifolium* in flower, especially around shell holes on foreground on right.

The vegetation of this region, once wrested from the sea, rapidly succumbed before the salt water—willows, poplars, elms, etc., all dying as the salt tide reached their roots. At Blankaert, where the waters of the Yser diluted the salt water, Massart figures

an interesting group of willows which, inundated for more than a metre above their normal root level, have developed a fresh crop of roots at the new water level, increasing the girth of their trunks above this new fringe of roots.

Very few plants replaced the displaced vegetation, and when the water retreated the mud was left bare and desolate. Massart describes the red alga, *Porphyra laciniata*, growing in the brackish water of a shell-hole, but no longer red in colour. Fringing the salt inundation were typical halophytes, like *Aster tripolium*, *Atriplex littoralis*, etc. As the waters receded and the former denizens returned to the attack these plants have to retreat—in 1919 in the ascendant throughout the region, 1920 finds them fighting desperately for a foothold upon the salt-incrusted edge of many a shell-hole. Active in the attack upon these war-time invaders is *Agropyrum repens*, a plant the fighting qualities of which are known to many an allotment holder. *Phragmites communis* had maintained itself during the inundation upon occasional islets rising above the general flood level, where it dispossessed practically all other inhabitants trying to maintain themselves before the salt flood. As the mud dries, long slender rhizomes descend from these little knolls and Phragmites eagerly advances to recover its old domain. An interesting observation made by Massart is that as the yellow-flowered halophyte *Aster tripolium*, typical of the salt marsh, recedes before the reconquering flora of the fertile Belgian plain of peace, there is a fringe of the form of this aster with purple-ray florets to be found maintaining itself for a time upon the more fertile, less saline soil. This occurrence of the purple form is being made the subject of further study in a biological laboratory installed upon the Yser.

Another result of the war is that some of the earlier scientific communications, republished from French scientific journals, give the observations made by Prof. Massart in his enforced exile during those tragic years, including a most interesting discussion of the striking features of the Riviera vegetation as they appear to a Belgian ecologist. The reprinting of Prof. Massart's polemical contribution to the *Revue de Paris* of October 1918, "Les Intellectuels Allemands et la Recherche de la Vérité," seems inappropriate in a volume of this nature, but the perusal of this article may be recommended to any British botanists who may have so far failed to realise the difficulties that still lie in the way of any genuine international Botanical Congress, of the type that would have been held in London before the present date if the war had not intervened.

Methods and Costs of Coal-mine Haulage.[1]

By Prof. HENRY LOUIS.

THE series of bulletins issued under the authority of the University of Illinois has achieved an enviable reputation among mining engineers in this country, and the latest addition fully sustains this reputation. Its origin differs slightly from preceding bulletins, inasmuch as it has been prepared under a co-operative agreement between the Engineering Experiment Station of the University of Illinois, the Illinois State Geological Survey, and the United States Bureau of Mines. Incidentally, such a method of work may be recommended to the serious attention of universities in this country; some of them have indeed moved in this direction, but none has gone so far as has the University of Illinois.

The present bulletin could scarcely come at a more opportune moment, seeing that attention in this country is being focussed upon the possibilities of electric locomotive haulage in collieries, and the pamphlet under review contains a full and authoritative exposition of what is being done in one of the most important of the coal-mining regions of the United States, Illinois ranking in coal output next to Pennsylvania, with an annual production exceeding one-third of that of Great Britain. Individual mines, moreover, are very large, seeing that in some of them, as is here stated, "6000 or more tons of coal per day are hoisted in 5-ton capacity cars and that 1200 or more cars per day, or 150 per hour," must be concentrated at the shaft bottom from various parts of the mine; there is nothing on the same scale in this country.

The bulletin is divided into six chapters. The first contains merely a brief introduction and explanation of the scope of the subject. The second chapter deals briefly with the evolution of mine haulage and shows how great has been the change in practice within the last twenty years: "In 1899, 87·1 per cent. of the tonnage in Illinois coal-mines was handled by animal haulage. Locomotives hauled 2·5 per cent., ropes 7·9 per cent., and tramming 2·5 per cent., but in 1921 it appears that both ropes and tramming were practically obsolete and that 91·2 per cent. of the coal was moved by locomotives, and only 8·8 per cent. by animals."

Of the locomotives, by far the greatest number are electric; considerable attention is now being paid to the track, 45- to 60-pound rails being used on the main roads. It appears that the first electric locomotive was tried in a colliery in Illinois so far back as 1888, but their introduction on any scale only came eleven years later. These locomotives were trolley locomotives and could only run on main roads; gathering from the coal face was still mainly done by mules, but in 1900 the cable locomotive was introduced, consisting of a locomotive furnished with a long flexible conducting cable carried on a reel, which enabled it to run on rails not equipped with trolley wires. For steep dips crab locomotives have been used, consisting of a locomotive with a separate motor driving a drum carrying a steel winding rope, by means of which cars could be hoisted up gradients too steep for the locomotive to travel. Another method of getting over the latter difficulty was the introduction of the rack-rail locomotive, similar to the type used on certain mountain railways.

Storage battery locomotives were introduced about 1899, and they have gradually been improved until their use is now very general; they are so built that they are considered quite safe for operation even in gassy mines. Other types of locomotives that are, or have been, used are steam locomotives, compressed air locomotives, and petrol locomotives; curiously enough, the so-called fireless locomotive using superheated water, which is quite popular in German collieries, appears never to have been even considered, although it no doubt presents certain advantages in fiery mines.

The third chapter of the bulletin deals with the lay-out of the shaft bottom; this section is of com-

[1] Engineering Experiment Station, University of Illinois. Bulletin No. 132: "A Study of Coal-mine Haulage in Illinois," by H. H. Stoek, J. R. Fleming, A. J. Hoskin.

paratively little interest to engineers in this country, as the underground arrangements differ so widely from what they do in America. Perhaps the most important point is the reference to skip hoisting, which has been introduced at several important shaft mines since 1918, the skips carrying loads of between 10 and 12 tons. At one of these mines a trial record of 1000 tons was hoisted in an hour, but all appeared to be capable of hoisting 7000 to 8000 tons daily. It must, however, be remembered that Illinois shafts are shallow, the average depth being only 225 ft.

The fourth chapter deals with details of methods of haulage, both on main lines and by gathering locomotives, which travel between the working face and the "partings" on the main lines; where locomotives are used for gathering, the length of secondary haulage ranges from 800 to 2000 ft. The operations are given in much detail and illustrated by tables of running times. It is shown, for example, that in a large colliery, where the average distance hauled on the main track is 4562 ft., a 15-ton locomotive hauls on the average 1035 ton-miles of coal per day and travels 24 miles. Gathering locomotives necessarily do very much less work than a main-line locomotive, the ton-mileage of the former being approximately $\frac{1}{18}$th of that of the latter. This chapter further contains much useful information upon the construction of mine cars, and directs attention to the efforts that have been made to standardise car design and construction. It is interesting to note that an Illinois mine requires about one car for every four tons of coal hoisted per day; in comparing this with British figures, the larger size of the American car and the shorter length of the main roadways must be taken into account. The construction of the colliery track both on main lines and also for secondary haulage is given in some detail.

Underground haulage costs are carefully dissected in the fifth chapter. There is some difficulty in comparing these costs with costs in this country, because in America costs of hoisting appear frequently to be included with those of haulage, under one head of transportation. It should also be noted in studying this chapter that the items of interest on plant and depreciation are not included. There is thus no real comparison possible between the cost of locomotive haulage and that of animal haulage, which in America always means mule haulage. The last chapter deals with accidents, and the importance of the subject is clear from the opening statement that "For the past ten years haulage fatalities have been second in importance only to those from falls." A dissection of the fatalities shows that the greatest number by far is due to men being caught and run over by cars or locomotives; it is interesting to note that in 1920 thirty-five deaths were due directly to the employment of electricity and four to animals, a proportion of approximately nearly 9 to 1, whereas it has been shown that in 1921 there was more than ten times as much coal moved by locomotives, the vast majority of which are electric, as was moved by animals, so that, contrary to what might have been expected, the danger to life attending the use of the two methods may be said to be about equal. The section concludes with recommendations for the prevention of accidents and a series of safety rules for underground haulage.

It will be fairly obvious from the above summary that this bulletin is one of very real value to the mining community, and deserves the most careful study and attention from coal-mining engineers in this country.

Science Teachers in Conference.

SCIENCE MASTERS' ASSOCIATION.

NEARLY 350 members of the Science Masters' Association assembled for their annual general meeting at Cambridge on Tuesday, January 2, when, by the kindness of the University authorities, they took up residence in Trinity and St. John's Colleges. In the evening the members assembled in the Large Examination Hall, where the general meeting and presidential address opened a crowded programme of scientific lectures and demonstrations. Responding to a general desire that the president should address the Association on some aspect of that branch of science which is so closely identified with his name, Sir Ernest Rutherford delivered an address on "A Decade in the History of the Electron." He reminded his audience of the characteristic and peculiar behaviour of the alpha particle and the evolution of our present ideas of atomic structure arising from the work of such investigators as Bohr, Laue, Moseley, and others. After referring to the essential features of radioactive disintegration, he passed to the consideration of the effect of the bombardment of atoms with swiftly moving alpha particles and concluded by outlining some more recent work in which he had been engaged: this aimed at throwing light on the mechanism by which electrons are captured, and released, by such particles.

A vote of thanks was proposed by Prof. Smithells, president-elect of the Association, and seconded by Sir Richard Gregory, and the meeting then passed to the election of officers for the ensuing year.

The following two days were largely absorbed by lectures, demonstrations in the various University laboratories, and visits to the University observatory, farm, and colleges; and if the parties visiting the colleges under the guidance of Sir Arthur Shipley, Dr. Rouse Ball, and others, were small, it must be attributed to the concentration of the scientific programme arranged, rather than to a lack of appreciation of the kindness of these gentlemen.

In addition to the presidential address, four lectures were delivered to the Association as a whole. On Wednesday morning, January 3, Prof. Seward, the Master of Downing College, lectured on "A Summer in Greenland," in the course of which he described his experiences during the summer of 1921 when on a tour of the coastal fringe of Greenland for the purposes of studying some of the botanical and geological features. Lantern illustrations accompanied his remarks on the evolution of icebergs, on dyke formations, on Eskimo life, and on the characteristic flora of the country. Prof. Seward, in addition to his description of topographical features, pointed out the remarkable sinkage in the land, and also the probable resemblance between Greenland to-day and England in the Ice Age.

On Wednesday evening the Chemical Lecture Theatre was crowded to hear Sir William Pope on the subject of "Crystalline Liquids." Prefacing his lecture by a short résumé of the properties associated with crystalline structure in the solid form, Sir William Pope proceeded to demonstrate, by the aid of the lantern-microscope, the existence of such a fundamentally crystalline property as double refraction in certain substances in the liquid condition, *e.g.* *p*-azoxyphenetole, *p*-azoxyanisole, and esters of cholesterol. The facile manipulation of these substances and the beauty of the polarisation effects shown on the screen were much appreciated.

Reference was made to the possible connexion between the molecular structure and the exhibition of anisotropic properties, and to the various theories that have been advanced to explain the peculiar properties of these somewhat unfortunately named liquids.

Thursday's activities were inaugurated by a lecture by the Master of Trinity on "The Electron in Chemistry." Sir J. J. Thomson apologised, as a physicist, for encroaching on the domain of the chemist, but added that the difference between chemistry and physics was due to want of knowledge, and that the problem of chemical combination was one of the most outstanding problems in physics. Dalton's Atomic Theory, as such, took no account of the intrinsic structure of discrete particles, and the modern conception of the internal arrangements of the atom dated from the discovery of the electron in 1897. The necessity of postulating a central positive nucleus and the possible arrangements of electrons around this was then discussed, and with the aid of diagrams and data thrown on the screen Sir Joseph reviewed existing knowledge of atomic structure, adequately deduced the existence of two forms of nitrogen, and showed that electrostatic considerations limited the number of electrons in a stable ring to eight. The latter part of his paper was devoted to the fascinating but somewhat intricate problem of chemical combination and the idea of "activated" molecules.

In addition to these lectures members of the Association divided to hear the very interesting and amusing lecture on "The Acoustics of Public Buildings," by Mr. A. Wood, and a lecture, equally attractive in its illustration, on "Coral Reefs in the Pacific," by Mr. F. A. Potts.

The scientific interests of the members were further selectively absorbed on Thursday by a lecture in the Anatomical Department by Dr. H. Hartridge on "Physiological Limits to the Accuracy of Visual Measurements"—a lecture of great interest to physicists among others—proceeding simultaneously with a lecture by Mr. E. K. Rideal on "Molecular Orientation on Plane Surfaces": in this, interesting deductions were made from the assumption that surface energy effects are restricted to a film of unimolecular thickness.

The visitors to the Cavendish Laboratory enjoyed Dr. Searle's demonstration of novel methods of determining physical quantities as well as the exhibit of apparatus used by Maxwell, Raleigh, Kelvin, Stokes, and other pioneer physicists. Prof. Marr prefaced his conducted tour of the Sedgwick Museum by a short lecture on some geological considerations suitable for school treatment, while demonstrations of great interest to those engaged in the teaching of science were set up in the laboratories devoted to chemistry, physical chemistry, metallurgy, botany, physiology, experimental psychology, zoology, mineralogy, and in the new Department of Engineering.

A conversazione in the Large Examination Hall on Thursday evening officially terminated the meeting (although the laboratories were opening on the Friday to provide further opportunities for those desiring to visit them): on this occasion Mr. R. E. Priestley lectured on "Antarctic Exploration with Shackleton and Scott." Mr. Priestley's amusing and thrilling lecture, accompanied by lantern illustration that won frequent applause, provided an appropriate conclusion to a richly stimulating meeting.

It remains to be mentioned that well-known firms held an exhibition of books and apparatus in the Arts School.

Association of Women Science Teachers.

At the annual meeting of the Association of Women Science Teachers held at University College, London, on January 6, a report was received from the subcommittee appointed to investigate the possibility of getting into touch with Colonial and foreign teachers of science. An appeal was made for members to correspond with teachers in other countries, and especially to send scientific journals to them. It is hoped that this movement may be further developed and become a useful part of international co-operation.

In her presidential address Miss M. B. Thomas reviewed the criticisms which have recently been made against methods of teaching science in schools. She pointed out that it was impracticable, under existing conditions, to combine preparation for university entrance examinations with the wide and more generalised scientific instruction which was so generally felt to be desirable, and pleaded for greater co-ordination between the subjects taught in schools. It was obvious that Science, and Languages, English, etc., could be mutually helpful, and that a closer co-operation between the mistresses teaching these subjects would result in advantage to all the subjects.

In the afternoon a large and appreciative audience heard a lecture by Dr. Dorothy Wrinch on "Relativity and Scientific Method." The lecturer gave an exposition of this difficult subject which was so clear that even her non-mathematical hearers could follow the argument. She pointed out that the old dynamics had rested entirely upon the idea of measurement relative to a rigid and stationary standard, and that if the standard moved with a uniform velocity the position of affairs was altered. Examples were quoted in which the new equation for the composition of velocities has solved long-standing problems. Dr. Wrinch then proceeded to apply the principle to various kinds of scientific problems, which must not be approached on the assumption that the old laws would hold good but with the possibility in view that some law of the same nature as that of relativity might be the governing principle. To sum up, it must be remembered that if such apparent fundamentals as time and distance have been shown to depend on velocity, then velocity is a relevant variable in all scientific method.

Hail and Sleet in Meteorological Terminology.

AT intervals there appears in the meteorological literature of various countries a discussion concerning the proper designation of the smaller and softer forms of hail which are common in all European countries during the winter or spring months. A recent contribution to the subject by R. Giacomelli, appearing in the issue for May and June of *La Meteorologia pratica*, the organ of the observatory of Montecassino, near Naples, is illuminating from certain points of view, without really settling the question. It is pointed out that the French and German terms, *grésil* and *gräupel* respectively, have the root idea of little pellets or grains, and that the real Italian equivalent, *gragnola*, is meteorologically a better descriptive term since it means "little hail." In full keeping, moreover, with the almost amusing richness of the Italian language in diminutive terms, one may use in place of *gragnola*

the words *granzola*, *granuschia*, *gragnolischia*, all of which are derived from *grandinola* (*grandine*, hail), and each of which is locally favoured in various parts of central Italy, where such forms of frozen precipitation are fairly frequent in the spring period, March and April.

In English we have no distinctive word, nor, as it is hoped to show in this note, do we really need one. The familiar word "sleet" appears to follow the German *Schlacken* in denoting a mixture of rain and snow in the British Isles; but in the United States "sleet" is officially reserved for true frozen rain, that is to say, drops which congeal into clear ice spherules by passing through a cold surface stratum of air. This kind of hail, as one would categorise it in England, is a common winter phenomenon in the eastern States, because there the contrasts of temperature between the equatorial and polar currents in cyclones, though not more frequent than in England, are more violent, so that a warm rain more often than here alights on a frozen soil. But, on the other hand, various forms of wintry hail falling in showers in moderately cold polar currents during the winter and spring are distinctly common in England, and these show almost every gradation from the little soft white opaque pellets, which are really hardened snowflakes and might be called "snow-hail," to something very like the real hail more typically associated with summer thunderstorms. It is clear that ambiguity would arise if "sleet" were used for any of these forms in this country. In fact, the British official practice of comprising all forms of frozen precipitation other than snow under the term "hail" is philosophically sound, and no regret need really be felt that we have no word to correspond to *grésil*, *gräupel*, or *gragnola*. It would appear that the only real solution of this terminological difficulty is to recognise but three fundamental species of precipitation: "rain," the liquid form; "snow," the frozen form in flakes or dust; and "hail," the frozen form in stones or pellets.

Actually, the different varieties of hail scarcely differ more from one another than do the different varieties of snow, or even of rain, and no difficulty need be felt on that score. Doubtful forms, such as the "snow-hail" referred to above, had best be entered in a register to both species; and in the case of the mixture of rain and snow, which in this country we call "sleet," this is habitually done. The double-entry plan has the advantage of tending to eliminate the effect of personal bias on the part of an observer, a factor which probably affects quite seriously the comparability of snow-frequency statistics in different localities. L. C. W. B.

The International Astronomical Union.

VOLUME I. of the Transactions of the International Astronomical Union, giving an account of the first general assembly held at Rome, May last, is edited by Prof. A. Fowler (London: Imperial College Bookstall, Prince Consort Road, S.W.7; price 15*s*.). It is an indispensable book of reference for astronomical workers, which contains the agenda of the thirty-two commissions, including important proposals for the co-ordination of methods of observing and mapping out of the fields of work to avoid useless duplication. The spectroscopic data are particularly full: the Draper spectral notation has been slightly modified and considerably extended in the light of increased knowledge. The letter Q is assigned to novæ, and the well-known stages in the development of the nova spectrum are indicated by suffixes. There is also a list of wave-lengths of iron, neon, and other lines suggested as standards.

Some of the decisions may be given briefly. The Latin names of the constellations are to be used, and a set of 3-letter abbreviations of these names was agreed to. The kilometre is to be used for line-of-sight velocities and for dimensions of bodies, the astronomical unit for planetary distances, the parsec for stellar distances. Absolute magnitude is defined as the magnitude at a distance of 10 parsecs. Certain letters were formerly used with several different meanings; they are now distinguished thus: [A] = a line in the spectrum, A or *A* (ital.) = Argon, A = a stellar spectral type.

The *Conn. des Temps* list of Fundamental Stars and the *Carte du Ciel* list of intermediary stars were adopted as standards, and 1925·0 is to be used as the standard equinox up to 1940. M. Andoyer undertook to reduce the latest positions of the fundamental stars to this equinox.

It was recommended that the short-period variations in solar radiation, announced by Abbot, should be studied as widely as possible, and their correlation with weather changes investigated.

Photometric work on minor planets was recommended. In stellar-parallax work it was recommended that plates of each field should be repeated after 10 years, to obtain the proper motions of the comparison stars.

A central bureau for double-star work was recommended, and various decisions for securing uniformity of method were passed. A variable star bureau or centre in each country is desirable (one has been established at Lyons). The Cracow Observatory undertakes the preparation of ephemerides of Algol stars.

The commission on calendar reform recommended (1) a perpetual calendar, with a 52-week year and one or two days outside week and month, (2) the lengths of the months in each quarter should be 30, 30, 31 days, and (3) that the year should begin at the winter solstice.

The volume is thus a noteworthy record of important decisions, embracing nearly every branch of astronomy.

The Haber Process.

THE lecture delivered by Prof. F. Haber on the award of the Nobel Prize at Stockholm on June 1, 1920, is printed in *Die Naturwissenschaften* for December 8. Prof. Haber dealt first with the work done on the synthesis of ammonia before his first research in 1905. Practically nothing of importance had come to light, and the very small yields at ordinary pressures did not hold out much promise of technical application.

The early experiments of Haber, like most of those which have served as the foundations of great industrial undertakings, were made with a purely scientific object, and with no technical applications in view. The results obtained, however, soon made it clear that the basis of an important technical process could be found in ammonia synthesis, and further work was undertaken with this end in sight.

In 1908 the Badische Gesellschaft placed at Haber's disposal all the means requisite for the further progress of the research on the synthesis of nitric oxide

in the electric arc which he had begun in 1907, but his proposal to undertake research on the synthesis of ammonia was received with open doubts as to the potential value of the method. The nitric oxide syntheses, in cooled arcs under reduced pressure, and in flames and explosions, were not found suitable for technical application, and attention was then turned to the stone which the builders had rejected. The judgment of the technical chemists of the Badische Gesellschaft had been at fault, since ammonia synthesis was ultimately a very real solution of the problem of the economic utilisation of atmospheric nitrogen.

Ramsay and Young in 1884 had found that with nitrogen and hydrogen in presence of iron at 800° C. no ammonia was produced. This was found to be incorrect, and traces of ammonia were detected. Other catalysts were tried, and from the results it was evident that an equilibrium state was attained, from which it was possible to calculate the yields at other temperatures and pressures. No further progress was made, however, since it was judged by the technical experts to be impossible to carry out the reaction on the large scale at the temperatures required under the very high pressures indicated by the calculations.

In 1906 measurements under pressure were for the first time carried out by Nernst and Jellinek (these are not referred to by Haber), and in 1908 Haber in conjunction with Dr. Le Rossignol began experiments at higher pressures. The work of Le Rossignol (a British subject) is spoken of with great approbation, although his part in the achievement of success has perhaps not always received full credit in some quarters. The technical chemists were still unfavourably inclined towards the process, although practical yields had now been reached: it was clear that "es eines eindrucksvollen Fortschrittes bedurfte, um das technische Interesse für das Gegenstand zu wecken." By the use of new catalysts the temperature was lowered to 500-600° under a pressure of 200 atmospheres. In 1913 the process was taken up by the Badische Gesellschaft, but an account of the main scientific results was also published. The work of Dr. Bosch speedily led to the successful introduction of the synthetic ammonia process, and in the period 1913–1920 the capacities of the German factories rose from *nil* to 35,000 tons per annum in 1914, 850,000 tons in 1918, and 1,500,000 tons in 1920.

University and Educational Intelligence.

CAMBRIDGE.—The annual report of the General Board of Studies on certain University departments shows much useful work being done both in instruction and research. Here we must limit ourselves to some of the new features. (1) It is announced that the enlargement of the Small Animal Breeding Research Institute with help from the Ministry of Agriculture has been followed by a proposal to place at Cambridge a Horticultural Research Station set up by the Ministry in conjunction with the growers. (2) The formation of the Cambridge Architects' Club to unite former members of the University within the profession in support of the School of Architecture is not valuable merely to the department concerned, but may react favourably in several ways on all departments of the University. (3) Research work is being carried out on aerial surveying, also on the measurement from aeroplanes of the altitude of the sun by means of gravity-controlled sextants, the aeroplanes and pilots being provided by the Air Ministry for work under the direction of the professor of aeronautical engineering. (4) The exhibit made by the School of Forestry at the Royal Agricultural Society's Show was awarded the Society's special gold medal.

LONDON.—A number of free public lectures have been arranged for the Lent term at King's College, Strand. A course of eight lectures, on Wednesdays, at 5.30 P.M., commencing January 24, on "Some Aspects of Natural Philosophy," will be given, and the following, in the order named, have promised to lecture: Prof. A. N. Whitehead, Sir Frank Dyson, Dr. J. S. Haldane, Dr. Dukinfield Scott, Prof. F. Soddy, Principal L. P. Jacks, Sir Herbert Jackson, and Sir Richard Gregory. Prof. H. Wildon Carr is giving six lectures on "Physical Causality and Modern Science" on Tuesdays, at 5.30 P.M., beginning February 20. In the department of psychology, Dr. William Brown is giving a course of three lectures on "Psychology and Psychotherapy" on Mondays at 5.30 P.M., commencing February 19. There is also a course of six lectures by Prof. V. Barthold, of the University of Petrograd, on "The Nomads of Central Asia," on Thursdays, which commenced on January 18, and three lectures, by Dr. J. H. Orton, on February 20, 22, and 23, at 5.15 P.M., on "The Bionomics of Marine Animals."

At University College, a course of ten public lectures on "The Micro-organic Population of the Soil" will be given by Sir John Russell and the staff of the Rothamsted Experimental Station in the lecture theatre of the Botanical department of the College, at 5 o'clock on February 5, 7, 12, 14, 19, 21, 27, and March 1, 5, and 7. Dr. G. Anrep is also to deliver a course of eight public lectures at the College, at 5 o'clock, on January 26, February 2, 9, 16, 23, and March 2, 9, and 16, on "The Physiology of the Cortex as investigated by the Method of Conditioned Reflexes." No tickets will be required for either of these courses.

THE Board of Education announces that the Imperial Education Conference is to be held in London in June next. The last meeting was held in London in 1911, and, but for the war, the conference would have met in 1915. The conference will be attended by official representatives from the Education Departments of the self-governing Dominions and Colonies and the British Isles, and various matters of common interest will be discussed, including the question of the interchange of teachers within the Empire.

THE trustees of the Albert Kahn Travelling Fellowships will elect one fellow in May or June next. These fellowships were established by M. Albert Kahn, of Paris, in order to enable suitable persons to undertake a year's travel round the world with the view of obtaining an unprejudiced survey of various civilisations and the acquisition of a generous and philosophic outlook on life. The value of the award for this year will be between 900*l.* and 1000*l.*, the exact amount being decided at the time of election. Candidates may be of either sex, but must be British subjects and graduates of a university of Great Britain or Ireland. The vice-chancellors of these universities, and the presidents of the Royal Society and the British Academy, may each nominate one candidate. Nominations must be sent in by February 28.

PROF. BOHUSLAV BRAUNER writes:—"John Gerald Frederick Druce, senior science master at Battersea Grammar School, London, has obtained the important degree of 'Doctor Rerum Naturalium' of the Charles' University, Prague, after having passed his examinations, which were conducted in English and French, 'summa cum laude.' Dr. Druce is the first Englishman to take this degree in the Charles' (Bohemian) University of Prague. This is the beginning of new scientific connexions between the Czech and English nations. *Vivant sequentes.*"

Societies and Academies.

LONDON.

Royal Microscopical Society, December 20.—Prof. F. J. Cheshire, president, in the chair.—J. E. **Barnard**: Sub-bacteria. The name "Sub-bacteria" is suggested for that group of presumably living organisms which are usually referred to as "filter passers" or "ultra-microscopical viruses." The term may be justified on the grounds that such organisms are of the same order of size as colloidal particles known as sub-microns. Filters are of variable and often unknown porosity, and it is therefore more satisfactory to let the microscopical limits of resolution be the standard beyond which the title suggested may be applied. For the investigation of bodies beyond the limits of microscopical resolution but still within the limits of visibility by suitable illumination, the improbability of any staining method proving of value was insisted on, particularly those involving prolonged fixation processes in which the so-called staining is in reality a deposition of material on the exterior of the object.—H. J. **Denham**: A micrometric slide rule. When one or more micrometer eyepieces are employed with several objectives, a simple nomograph may be used to convert the eyepiece measurements into known units of length. The slide rule described consists of such a nomograph fitted with a movable cursor, which is engraved with an eyepiece scale enlarged ten times. Oblique rulings on the body of the scale represent the rulings of a stage micrometer. The scale is calibrated by trial of the various combinations of eyepiece and objective likely to be used (at standard tube length) on a graduated stage micrometer: to use it, the movable cursor is set to the predetermined position for the combination of eyepiece and objective employed, and the eyepiece measurement is read off in terms of the stage micrometer, while the magnification may be read off the graduated lower edge of the rule. Correction for alterations in tube length without recalibration may be made by the help of a second nomograph on the back of the slide rule.—J. R. **Norman**: Methods and technique of reconstruction. Some of the methods employed for building up a model of any object which has previously been cut into sections in a definite plane are described. The Graham Kerr method consists in making coloured drawings of the sections on ground-glass plates; the plates are then fitted together, and a model obtained by rendering them transparent by immersion in a suitable medium. In the so-called "plastic" method invented by Born, which appears to be in general use, the sections are drawn on plates made of some form of wax, their outlines cut out, and the wax sections fixed together to form a solid model. The technique of preparing the models is described and a new wax mixture formulated.

PARIS.

Academy of Sciences, December 26.—M. Emile Bertin in the chair.—Pierre **Termier**: The structure of the eastern Alps; origin of the superalpine sheet; the problem of the age of the large strata.—A. **Blondel**: The electro-phonographic method and its use for the registration of sounds. The author described in 1911 a method of sound recording based on the combination of the microphone and oscillograph, and this was modified in 1915 for use under war conditions. An imperfect form of this was utilised, without acknowledgment, by the French army.—C. **Guichard**: Conjugated networks.—Edouard **Imbeaux**: The fountain of youth (Silver Spring). A description (with photograph) of Silver Spring, Florida, with a geological section showing its relationship with Blue Spring, 26 miles distant.—Alf. **Guldberg**: Some inequalities in the calculus of probabilities.—Bertrand **Gambier**: Linear systems of plane curves admitting a given system of base points.—Georges **Bouligand**: A concept of linear geometry.—Nilos **Sakellariou**: Polar figures.—A. **Petot**: Motor-cars with transmission by a longitudinal Cardan shaft.—M. **Maggini**: Anomalous dispersion in stellar spectra. Studies on anomalous dispersion may serve as a qualitative test of the theories of Lockyer and Schuster on the evolution of stars.—J. **Le Roux**: Newton's mechanics is not an approximation of that of Einstein.—F. **van Aalst**: The maintenance of electrical oscillations by a lamp with three electrodes. Experiments confirming the formula expressing the necessary condition for the maintenance of oscillations.—A. **Druault**: The diffraction spectra produced by round corpuscles irregularly distributed. Three classes of round corpuscles were used in these experiments, lycopodium grains, powder from diseased wheat, and red-blood corpuscles. The existence of a maximum of diffracted light not predicted theoretically is shown.—H. **Weiss** and P. **Henry**: Diffusion in solid solutions. A study of the interdiffusion of gold and silver at temperatures of 935° C., 885° C., and 835° C. The diffusion constant found agrees well with the earlier figure of Fraenkel and Houben at 870° C.—F. **Bourion** and E. **Rouyer**: The application of the method of continuous variations to boiling-point phenomena for the determination of double salts in solution.—Marcel **Delépine**: The *cis* and *trans* iridio-dichloro-dioxalates. The optical resolution of the *cis* potassium salt.—Marcel **Godchot** and Pierre **Bedos**: The oxide of Δ_3-methylcyclohexene and the dimethylcyclohexanols. The ether oxide can be obtained from the hydrocarbon Δ_3-methylcyclohexene either by direct oxidation with perbenzoic acid or by conversion into the iodohydrin and subsequent treatment with caustic potash. The ether oxide is converted into the corresponding diol by heating with water for six hours at 130° C.—Paul **Gaubert**: The polymorphism of antipyrine, vanillin, and the erythrites.—M. **Lecointre**: The palæozoic strata of the region north-west of Zaër (Western Morocco).—Georges **Corroy**: The Valanginian of the eastern border of the Paris basin.—M. **Boit**: The morphology of the Bas-Morvan.—Marc **Dechevrens**: Two categories of earth currents. A discussion of various observations from 1851 onwards from the point of view of the influence on the moon on telluric currents.—C. **Dauzère**: Researches on natural coloration effected at the Pic du Midi according to the experiments of J. Bouget. The intense colorations of flowers at high altitudes are ascribed to the same cause as the permanent coloration of glass exposed in similar positions.—Ph. **Flajolet**: Perturbation of the magnetic declination at Lyons during the year 1921–22.—R. **Dongier**: Magnetic measurements in the south-east of France (left bank of the Rhône).—L. **Blaringhem**: Hereditary mosaic in the pea (*Pisum sativum*).—René **Souèges**: The embryology of the Malvaceæ. The development of the embryo in *Malva rotundifolia*.—E. and G. **Nicolas**: The influence of formaldehyde on the higher plants. When chlorophyll is absent, or present in insufficient quantity, formaldehyde exerts a toxic action on plants: when the chlorophyll can act as a photocatalyst the influence becomes favourable to growth.—Manuel **Sánchez y Sánchez**: The nature and function of the reticular apparatus of Golgi. The process of oxidation in the plant cell and the development of the network of Golgi increase together;

hence it appears probable that in the Golgi apparatus ferments indispensable to the nutrition and development of the cell are produced.—H. **Colin** and H. **Belval**: The genesis of the carbohydrates in wheat. The presence of levulosanes in the stem.—C. **Champy**: The fluctuating appearance of the male sexual characters in the female *Triton alpestris*.—Edouard **Chatton** and André **Levoff**: The evolution of the infusoria of the lamellibranchs. Relations between the Sphenophryidæ and the Hypocomidæ.

Diary of Societies.

SATURDAY, JANUARY 20.

BRITISH MYCOLOGICAL SOCIETY (in Botany Department, University College), at 11 A.M.—Dr. W. Brown and Dr. A. S. Horne: Fusarium.—J. Ramsbottom: Berkeley and Broome.—Miss W. Ridler: The Fungus present in *Lunularia cruciata*.—Dr. H. Wormald: Crown-Gall in Nursery Stock.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Walford Davies: Speech Rhythm in Vocal Music (1).

MONDAY, JANUARY 22.

ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge), at 5.—P. Lake: Wegener's Hypothesis of Continental Drift.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—A. G. Warren and others: Discussion on Insulators and Insulating Materials.

INSTITUTION OF MECHANICAL ENGINEERS (Graduates' Section), at 7.—Informal Discussion on The Value of College Training to Engineers.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—R. Knott and W. E. Riley: The London County Hall.

ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8.—Sir William Willcox and others: Discussion on Dental Sepsis as an Etiological Factor in Disease of other Organs.

TUESDAY, JANUARY 23.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. F. G. Donnan: Semi-Permeable Membranes and Colloid Chemistry (2). Relation to Problems of Colloid Chemistry and Biology.

INSTITUTION OF CIVIL ENGINEERS, at 6.

INSTITUTE OF MARINE ENGINEERS, INC., at 6.30.—Film illustrating Industrial Works.—Messrs. Beardmore, Ltd.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—F. C. Tilney: Address.

ROYAL ANTHROPOLOGICAL INSTITUTE (Anniversary Meeting), at 8.15.

WEDNESDAY, JANUARY 24.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—Rev. C. Overy: The Glacial Succession in the Thames Catchment-Basin.—Dr. S. H. Haughton: Reptilian Remains from the Karroo Beds of East Africa.

WOMEN'S ENGINEERING SOCIETY (at 26 George Street, Hanover Square), at 6.15.—Miss V. Holmes: Mechanical Injection of Fuel as applied to Diesel Engines (to be followed by a Discussion).

ROYAL MICROSCOPICAL SOCIETY (Section dealing with the Industrial Applications of the Microscope), at 7.—Inaugural Meeting.—Prof. F. J. Cheshire: Opening Address.—Dr. F. J. Brislee: Training in Practical Microscopy and the Necessity of providing Facilities for more Definite Instruction.—Dr. J. S. Owens: Atmospheric Pollution.—Demonstrations.—Exhibits.

ROYAL SOCIETY OF ARTS, at 8.—Sir William Henry Bragg: The New Methods of Crystal Analysis, and their Bearing on Pure and Applied Science ("Trueman Wood" Lecture).

BRITISH PSYCHOLOGICAL SOCIETY (Medical Section) (at Royal Society of Medicine, 1 Wimpole Street), at 8.30.—Dr. W. Brown: Autosuggestion and Transference.

THURSDAY, JANUARY 25.

ROYAL SOCIETY, at 4.30.—*Probable Papers*.—Prof. A. V. Hill: The Potential Difference occurring in a Donnan Equilibrium and the Theory of Colloidal Behaviour.—Dr. E. F. Armstrong and T. P. Hilditch: A Study of Catalytic Actions at Solid Surfaces. X. The Interaction of Carbon Monoxide and Hydrogen as conditioned by Nickel at relatively low Temperatures. A Practical Synthesis of Methane.—Dr. J. Holker: The Periodic Opacity of certain Colloids in progressively increasing Concentrations of Electrolytes.—E. K. Rideal and R. G. W. Norrish: The Photochemistry of Potassium Permanganate. Part I. The Application of the Potentiometer to the Study of Photochemical Change. Part II. On the Energetics of the Photo-decomposition of Potassium Permanganate.—E. A. Fisher: Some Moisture Relations of Colloids. I. A Comparative Study of the Rates of Evaporation of Water from Wool, Sand, and Clay.—R. Whytlaw-Gray, J. B. Speakman, and J. H. P. Campbell: Smokes—A Study of their Behaviour and a Method of determining the Number of Particles they contain.—R. Whytlaw-Gray and J. B. Speakman: A Method of determining the Size of the Particles in Smokes. Part II.—R. C. Ray: The Effect of Long Grinding on Quartz (Silver Sand).

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7.30.—W. Day: The Birth of Cinematography and its Antecedents.

INSTITUTION OF STRUCTURAL ENGINEERS (at 296 Vauxhall Bridge Road), at 7.30.—W. J. H. Leverton: The Relations between the Architect and the Engineer.

CAMERA CLUB, at 8.15.—W. Wrench: Our Old Village Churches and their Story.

ROYAL SOCIETY OF MEDICINE (Urology Section), at 8.30.—Clinical and Pathological Meeting.

FRIDAY, JANUARY 26.

ASSOCIATION OF ECONOMIC BIOLOGISTS (in Botanical Lecture Theatre, Imperial College of Science and Technology), at 2.30.—Prof. R. T. Leiper: The Study of Helminthology.

ROYAL SOCIETY OF MEDICINE (Study of Disease in Children Section), at 5.—Special Clinical Meeting.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science and Technology), at 5.—J. J. Manley: A Further Improvement in the Sprengel Pump.—Dr. C. Chree: A Supposed Relationship between Sunspot Frequency and the Potential-Gradient of Atmospheric Electricity.—Dr. D. Owen: Null Methods of Measurement of Power-Factor and Effective Resistance in Alternate-Current Circuits by the Quadrant Electrometer.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—G. F. Shotter: K.V.A. and its Measurement.

ROYAL SOCIETY OF MEDICINE, at 8.30.—Special Meeting to commemorate the Centenary of the Death of Edward Jenner.—Sir W. Hale-White: Jenner and his Work.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Sir Almroth Wright: The Machinery of Anti-Bacterial Defence.

SATURDAY, JANUARY 27.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Walford Davies: Speech Rhythm in Vocal Music (2).

PUBLIC LECTURES.

MONDAY, JANUARY 22.

IMPERIAL INSTITUTE, at 3.—Miss Edith Browne: West Africa and Empire Production. (Succeeding Lecture on January 29.)

TUESDAY, JANUARY 23.

IMPERIAL INSTITUTE, at 3.—Col. M. C. Nangle: The Empire in the Far East. (Succeeding Lectures on January 24, 30, 31, February 6, 7, 13, 14, 20, 21, 27, 28, March 6, 7, 13, 14, 20, 21, 27, and 28.)

SOCIOLOGICAL SOCIETY (at 65 Belgrave Road), at 4.45.—Dr. C. W. Saleeby: Sunlight and City Life.

KING'S COLLEGE, at 5.30.—Miss Hilda D. Oakley: The Enigma of Socrates. (Succeeding Lectures on January 30 and February 6 and 13.)

GRESHAM COLLEGE, at 6.—Sir Robert Armstrong-Jones: Physic. (Succeeding Lectures on January 24, 25, and 26.

WEDNESDAY, JANUARY 24.

KING'S COLLEGE, at 5.30.—Dr. A. N. Whitehead: The Quest of Science To-day, and as exemplified in its History.

FRIDAY, JANUARY 26.

METEOROLOGICAL OFFICE (South Kensington), at 3.—Sir Napier Shaw: Forecasting Weather. (Succeeding Lectures on February 2, 9, 16, 23, and March 2, 9, 16, 23.)

UNIVERSITY COLLEGE, at 5.—Dr. G. Anrep: The Physiology of the Cortex as investigated by the Method of Conditioned Reflexes. (Succeeding Lectures on February 2, 9, 16, 23, and March 2, 9, and 16.)

SATURDAY, JANUARY 27.

HORNIMAN MUSEUM (Forest Hill), at 3.30. Capt. W. H. Date: Wireless Telephony and Broadcasting.

NEGRETTI & ZAMBRA
38, HOLBORN VIADUCT, E.C.1.
LONDON.

UNIVERSITY OF LONDON.

A Course of ten Lectures on "THE MICRO-ORGANIC POPULATION OF THE SOIL" will be given by SIR JOHN RUSSELL, F.R.S. (Director), and STAFF OF THE ROTHAMSTED EXPERIMENTAL STATION in the Lecture Theatre of the Botanical Department at UNIVERSITY COLLEGE, LONDON (Gower Street, W.C.1), on FEBRUARY 5, 7, 12, 14, 19, 21, and 27, and MARCH 1, 5, and 7, 1923, at 5 P.M. At the first Lecture, the Chair will be taken by Professor J. B. FARMER, F.R.S. ADMISSION FREE, WITHOUT TICKET. A Syllabus of the Lectures is obtainable on application to the undersigned.

EDWIN DELLER, Academic Registrar.

RESEARCH FELLOWSHIPS IN ACOUSTICS.

THE RIVERBANK LABORATORIES AT GENEVA, ILLINOIS, announce the establishment of one or two RESEARCH FELLOWSHIPS in ACOUSTICS. The holder will have an opportunity to devote his entire time to study and investigation in a laboratory built, equipped, and manned for the study of acoustic problems. Candidates should be college graduates who have taken advanced courses in physics and mathematics, and who have shown in their work those qualities essential for success in independent investigation. Terms of appointment to be determined by the qualifications of the appointee. Address, B. CUMMING, Secretary, Geneva, Illinois.

BATTERSEA POLYTECHNIC

LONDON, S.W.11

Award of Tate Scholarships for Session 1923-24.

The examinations for the award of SCHOLARSHIPS in ENGINEERING, SCIENCE, and DOMESTIC SCIENCE, will be held on Tuesday, June 5, 1923, and the succeeding days. The scholarships vary in value from £20 to £30 per annum with free tuition, and are tenable for two or three years.

Last day of entry April 21, 1923.

Full particulars on application to the PRINCIPAL.

UNION OF SOUTH AFRICA.

VACANCY FOR A RESEARCH ASSISTANT (MYCOLOGIST) IN THE BOTANICAL DIVISION OF THE DEPARTMENT OF AGRICULTURE.

SALARY.—£300-325-380×30-650 plus local allowance if stationed in an area where such is payable.

The commencing salary on the scale will depend on the selected candidate's qualifications.

ENGAGEMENT.—On twelve months' probation.

QUALIFICATIONS.—A University Degree; candidates must have taken Botany and its allied sciences for their final examination. Married women are not eligible.

TRANSPORT.—Free first-class train and steamer fares from residence to destination in South Africa; also in reverse direction if not appointed to permanent staff after probationary period.

Half salary during voyage to South Africa.

Applications, together with copies of testimonials as to qualifications and experience, all in duplicate, must be lodged, not later than February 9, 1923, with the SECRETARY, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C., from whom Forms of Application and further particulars may be obtained.

CITY OF BIRMINGHAM.

The Board of Research for Mental Diseases (University of Birmingham and the City Asylums Committee) require the services of a RESEARCH OFFICER to work under the HONORARY DIRECTOR, Sir FREDERICK MOTT. Preference will be given to a medical man who has taken the B.Sc. degree, or who has a good knowledge of Organic Chemistry. Salary £500 per annum (with possible residence).

Applications endorsed "Pathologist" must be received by the undersigned not later than January 31, 1923.

WM. HUTTON, Hon. Secretary.

Council House, Birmingham,
January 1923.

LEICESTER MUSEUM.

ASSISTANT required with knowledge of Palæontology and Invertebrate Zoology. Museum experience desirable. Commencing salary £250 per annum. Applications accompanied by copies of three recent testimonials to be delivered on or before February 25, addressed to the DIRECTOR, The Museum, New Walk, Leicester.

MINISTRY OF AGRICULTURE AND FISHERIES.

Applications are invited for an appointment as ASSISTANT (Herbarium) in the Royal Botanic Gardens, Kew.

Candidates, male or female, must be not less than 25 years of age and should be Honours graduates of a British University and have spent at least 2 years in Botanical Research or have had at least 2 years' experience in Systematic Botanical work since graduating. Such experience should include investigation of problems in either (*a*) Systematic Botany, (*b*) Plant Morphology, (*c*) Plant Physiology, Ecology, or Genetics, (*d*) Economic Botany, or (*e*) Cryptogamic Botany. Candidates must also produce evidence of ability to translate from either French or German.

Salary: (*a*) Male Assistant, £250 per annum, rising to a maximum of £600 per annum.

(*b*) Female Assistant, £200 per annum, rising to a maximum of £450 per annum.

In each case plus Civil Service bonus.

Preference will be given to ex-service applicants.

Forms of application can be obtained from the SECRETARY, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1, and must be returned not later than February 19.

COUNTY BOROUGH OF WEST HAM.

ESSEX MUSEUM OF NATURAL HISTORY,

ROMFORD ROAD, STRATFORD, E.15.

Applications are invited for the position of FULL-TIME ASSISTANT in the MUSEUM from persons having a practical knowledge of Museum Work.

Applicants should have had some biological training, and must be experienced in taxidermy and be able to mount and set up specimens and prepare dissections for exhibition, and should be capable of preparing diagram-drawings and taking photographs to illustrate exhibits. The possession of a Science Degree of a British University, although desirable, will not be considered essential if other qualifications are satisfactory.

The salary will be at the rate of £150 per annum plus Civil Service Award.

Applications to be sent by February 1, 1923, to the PRINCIPAL of the West Ham Municipal College, Romford Road, E.15, from whom particulars and forms of application may be obtained.

GEORGE E. HILLEARY, Town-Clerk.

January 5, 1923.

UNIVERSITY OF EDINBURGH.

LECTURESHIP IN GEOGRAPHY.

In consequence of the retirement on September 30 next of Mr GEORGE G. CHISHOLM, M.A., B.Sc., Reader in Geography, the University Court will proceed to the appointment of a LECTURER who will be responsible for, and in charge of, the teaching of this subject. The status of Reader may be attached to the office.

The salary is £700 per annum.

The appointment, which is subject to the conditions of the Federated Superannuation Scheme for Universities, will date from October 1, 1923.

Applications, 14 copies of which should accompany the principal application, should be sent to the SECRETARY not later than WEDNESDAY, February 28.

WILLIAM WILSON,
Secretary to the University.

UNIVERSITY COLLEGE, READING.

FACULTY OF AGRICULTURE AND HORTICULTURE.

Agricultural Costings Officer.

The Council will proceed shortly to the appointment of an AGRICULTURAL COSTINGS OFFICER, who, in addition to possessing a good general knowledge of Economics (preferably a degree qualification), should have had subsequent experience in Statistics or Accountancy with an Agricultural bearing.

Stipend, £450 per annum, together with 10 per cent Contribution to Superannuation Fund.

For further particulars apply to the REGISTRAR, University College, Reading.

LADY, B.Sc. (chemistry, metallurgy, physics), shorthand, typing, requires post. Box 50, c/o NATURE Office.

MANUSCRIPTS, ETC., TYPED neatly and accurately. Price 3d. per page, quarto (4d. foolscap); carbon copies ½d. per page. All kinds of technical, literary, or general work accepted. Mrs. SNOW, 28 Greenside Road, Shepherds Bush, W.12.

FOR SALE.—EDINGER APPARATUS, LEITZ. Leitz objectives. New condition. £40. Seen by appointment. 22 Smithambottom Lane, PURLEY.

The Science and Practice of Pure Milk Supply.

I.

THE history of our milk supply, especially when considered in relation to the corresponding history of the milk supply of the United States, illustrates more intimately, perhaps, than any other subject the necessity for the man of science to study the practical problems involved in the application of his discoveries, and for the administrator and the producer and trader to acquaint themselves with the added responsibilities and increased possibilities of improved trade bestowed by science.

We are chiefly concerned in NATURE with the scientific aspects of the milk problem; but at every stage these are interlocked with practical problems requiring the expenditure, or more correctly the investment, of much money to ensure the health of the community. A statement of some of the considerations involved will make these points clear.

The first point we make is frequently overlooked. An increase in the quantity of milk available for the general public, and particularly for children, is even more important than improved quality of the milk, though this also is a public health requirement of the first grade. In this country far too little milk is consumed. Biologists and chemists have demonstrated that no other food is so vital to the welfare and health of mankind as milk. McCollum, of Baltimore, has laid down the rule that every growing child should be allowed one quart of milk daily, and Lusk states that "no family of five should buy meat until they have bought at least three quarts of milk" daily. In Great Britain not half as much milk is consumed per head as in the United States, and it is to the lack of this element in the dietary of children that a large share of the common malnutrition and undergrowth, and the associated excessive proneness to disease is ascribable. There are abundant instances in which the daily giving of half a pint of milk to each child attending school in poor neighbourhoods has been followed by a marked raising of the general standard of health.

The above statement that an adequate quantity is even more important than an improved quality of milk, although it truthfully represents a neglected aspect of the milk problem, is obviously subject to the condition that milk of the present quality must be made safe either by pasteurisation on the large scale or by bringing it domestically near the boiling point.

Alongside of educational propaganda in favour of purer milk there is needed steady and persistent instruction through child welfare centres, in schools, and generally, to induce parents to spend on milk the greater part of

the money now devoted to beer. At the present time three times as much is spent by the British public on alcoholic drinks as on milk, and to this avoidable physiological impoverishment of the children, which is associated with the deficiency of milk, we can in large measure ascribe the proneness to catarrhs and the development of bronchitis, of rickets, and of tuberculosis.

Early, then, in any attempts at practical reform must be placed the need for educating the public into willingness to buy more milk—at least twice or three times as much as is now being bought, for daily dietetic use. It follows that any measures proposed for the purification of milk must be tempered by consideration of the degree of risk to health, the administrative practicability of the proposals, and the expenditure involved.

The necessity for milk sanitation, as for general sanitation, was first impressed on the public mind by the occurrence of epidemics attributed to contaminated milk. It was in 1857 that Dr. W. M. Taylor, of Penrith, traced an epidemic of typhoid fever to contaminated milk, and ten years later he traced an outbreak of scarlet fever to milk. In 1880 Mr. Ernest Hart collected accounts of fifty epidemics of typhoid, fifteen of scarlet fever, and four of diphtheria traced to infected milk supplies; and since then the number has become immensely greater, until, in recent years, commercial pasteurisation combined with a modicum of sanitary precautions on the farm and in the retailing of milk has been associated with a great decrease in the number of such outbreaks. In addition, septic sore throats have not infrequently been traced to milk derived from cows with udder inflammations; and, most important of all, a considerable proportion of human tuberculosis, especially in young children, has been attributed to milk.

The history of the relation of human to bovine tuberculosis is an interesting chapter in bacteriology. In 1896 Theobald Smith announced that the tubercle bacillus of cattle differed materially from that of human tuberculosis. In 1901 Koch made the sensational announcement in London that bovine tuberculosis did not infect human beings. Inasmuch as, prior to this statement, the stress of anti-tuberculosis agitation had been much more against bovine than against human sources of infection, Koch's dictum necessitated a re-investigation of the entire subject. A Royal Commission was appointed, and continued its inquiries for many years. The results of these and of many collateral investigations may be summed up in the statement that bovine tuberculosis undoubtedly does occur in the human being, but that it is a minor cause of human tuberculosis. Furthermore, that, unlike infection of human origin, bovine infection can be effectively prevented—as can also the infection of such occasionally milk-borne diseases as scarlet fever, typhoid fever, and diphtheria,—by pasteurisation of milk, or by bringing milk domestically "just to the boil."

It was tuberculosis in the young subject which was regarded as chiefly caused by milk infection, but experimental observation of the type of bacillus found in children's tuberculous lesions has shown that less than one-third of tuberculosis in children under five years of age is of bovine origin, the greater part being derived from infection of human source. The abdominal tuberculosis and tuberculosis of joints and bones and of glands, which may be due to infection of bovine source, are often not fatal; and it appears likely that, as Cobbett [1] has estimated, the mortality caused by infection with the bovine type of tubercle bacillus *at all ages* is not more than six per cent. of that caused by bovine and human types of bacillus combined. This estimate was made several years ago. The proportion of human mortality from tuberculosis due to bovine infection is probably less now, for one of the striking features of tuberculosis mortality is its recent reduction at ages under five. Thus the death-rate from tuberculosis per million living at ages under five was 1213 in 1920, as compared with an average rate of 1883 in 1912–14. Inasmuch as only a relatively small proportion of this mortality in the earlier period was caused by infected milk, the main credit for the decline, after making any needed allowance for changes in medical certification, must be given to the diminution of human infection; and the entire result can reasonably be regarded as the joint product of measures for diminishing bovine tuberculosis, which, speaking nationally, have been on an extremely small scale, of measures for rendering bovine infection impotent (pasteurisation of milk and domestic heating), and of measures directed chiefly against human adult sources of infection. We have mentioned the six per cent. as a possible limit of the proportion of total tuberculosis mortality at all ages which is due to bovine infection, without intention to minimise its importance, for the annihilation of tuberculosis of bovine origin would greatly reduce the mass of human suffering, and this end is within reach by easily practicable measures, which would serve the interest of dairymen as much as that of the consumers of milk.

The possibility of acquiring tuberculosis or an acute infectious disease like scarlet fever, although the chief, are by no means the sole risks of contaminated milk. Past experience has shown an intimate association between an impure milk supply and excessive infant mortality; and the remarkable reduction in

[1] L. Cobbett. "The Causes of Tuberculosis," Cambridge University Press, 1917.

infant mortality in the present century in this and in other countries has been associated with marked improvement in the cleanliness of milk, commercially and domestically. At each step scientific investigations have been important means to this end. The determination of the thermal death-point of pathogenic bacteria has shown the possibility of heating milk to a lower point than boiling, which, while removing the possibility of infection, leaves milk with its natural taste almost unimpared. The bacterial counting of milk, showing the close association between cleanly milking followed by immediate cooling of milk, and a sparse bacterial count has given a great impetus to the supply of clean and cool milk, especially in America. The tuberculin test has been largely utilised as a means of discovering clinically undiagnosable tuberculosis in cattle, and of its elimination from herds. It is a condition of the official granting of a certificate of production of "Grade A (Tuberculin Tested)" Milk, in accordance with a recent Order of the Ministry of Health. The discovery in 1890 of Babcock's simple method of fat determination has had far-reaching consequences in securing high standards of food value in milk supplies, and in enabling the public when they desire to buy milk of known value. The list of items of indebtedness of the public and of milk purveyors to scientific laboratory workers might easily be extended.

In England there is a large excess of infant deaths in the three hottest months of the summer, and these are due in the main to diarrhœa. To discuss adequately the factors of heat, of impurity of food, of impurities apart from food (*e.g.* exceptionally in breast-fed babies) which are responsible for this devastating disease would require much space; but the following determined facts can be stated. Diarrhœa is rare in breast-fed infants; it is exceptional among the infants of the well-to-do, who can take adequate precautions in respect of food; but it is common in the infants of the poor, and has been found to be more common in infants fed on condensed milk than in infants fed on fresh cows' milk. This does not apply to dried or desiccated milk, infants consuming which appear to suffer much less from diarrhœa than infants artificially fed with other foods. The explanation of these facts is not far to seek. Domestic contaminations of milk are even more important than contaminations at the farm, in transport, or in the local shop, though these also are serious. Condensed milk is difficult to manipulate in a cleanly manner, dried milk is not so. Fresh milk can be more easily provided and, when domestically pasteurised, has been shown to be less liable to cause gastro-intestinal trouble in the summer months than diluted condensed milk. The details showing the need for aseptic precautions in milk preparation, all based on the science founded by Pasteur and applied by Lister, can easily be understood. In the last seventeen years active steps have been taken to instruct and guide mothers in the right feeding of their infants, and there can be little hesitation in ascribing the lowered infant mortality in large measure to this cause, and to the collateral general improvement in the milk as delivered at the home. This improvement has consisted largely in the increasing practice of commercial pasteurisation. Prior to 1900 the rate of infant mortality averaged 140 to 160; in the last quinquennium it was only 85 per 1000 births.

The above consideration of evils and of possible channels of improvements naturally leads to a consideration of the administrative aspect of the problem. This in the main consists in the application of scientific methods to the milk industry, which will be discussed in our next issue.

Progressive Meteorology.

(London: H.M. Stationery Office, 1921–1922.)

ON turning over this packet of the latest official publications on meteorology I feel disposed to survey them in a contemplative rather than in a critical

attitude. They fall into two groups. The Catalogue of Meteorology in the Science Museum reviews the present in the light of the past, and the various publications of the Meteorological Office of the Air Ministry deal with the present in anticipation of a greater future.

Meteorology in a museum is something of a problem, for it is impossible to place samples of weather in a glass case, or at least to keep them there when the fog clears away, and the representation can be only by instruments, maps, diagrams, and models. The collection of instruments is intended to represent historical development and present-day adaptations, and the Catalogue gives a short description of the exhibits, following a brief historical introduction on each group of instruments. The number catalogued is considerable and achieves a fair historical continuity. Their ownership is left curiously vague; some are recorded as presented to the museum, but many are stated to be lent by well-known meteorologists, most of whom are now dead, so that it is scarcely likely that their return will be demanded. We note one misprint in the name of Prof. Mohn, who is consistently called Möhn, possibly under the influence of Föhn. A reference should be given to "British Rainfall," 1908, p. 25, for the principle of the Hyetograph (No. 206), from which the originator as well as the patentee of the instrument could be ascertained.

The exhibits other than instruments are scrappy and of little value as illustrations of the scientific developments of meteorology, but time and some fostering care should remedy this.

Turning to the side of present effort which faces the future, one looks on a new world. For thirty years, from 1882, I read every contribution to meteorology published accessibly in the English language and a good deal in other tongues. For the last ten years I have read practically nothing, and now find that a vast river of new research and discovery separates me from the old familiar country where Buchan ploughed his lonely furrow and sowed the seed of upper-air research on the inhospitable summit of Ben Nevis. How wide and deep that river is I recognise when in the preface to Mr. Pick's "Short Course in Elementary Meteorology" I find the Director of the Meteorological Office saying:

"The British Empire has produced some of the world's foremost meteorologists—Halley, Beaufort, Abercromby, Blanford, Eliot and Shaw, to mention only a few."

No Buchan and no Aitken among these immortals! An oversight of a too busy man, of course, but significant of the new horizons on which the great figures of the immediate past stand out in view of the men who are reaping the harvests now maturing. It is the natural fate of pioneers to be buried in the foundations they lay for others to build on, and the fundamental nature of their work may remain unrecognised until the historians of a later generation tunnel amid the ruins of successive superstructures to find material for some science museum. Anyhow, it is certain that the enterprise of the students of to-day is put to better purpose in pushing onwards rather than in looking back. The war is responsible for the abruptness of the overturn which has buried much of the past before it is dead, and now affords to the young men an unencumbered field.

In Mr. Pick's work and Dr. Simpson's preface it is good to find strong grasp of essential principles, a discriminating disregard of irrelevant detail, and an easy command of concise and vigorous English. It would serve no purpose to regret omissions from so short a treatise on so great a subject. There is a wise abstention from the use of long words when short words serve better, and indeed the only lapse into this besetting fault of youth I have noticed is the use of the terms "katabatic" and "anabatic" with reference to the valley winds by night and day; this just serves to quicken a sense of thankfulness that we are spared "katapelagic" and "anapelagic" attacks on the land and sea breezes or even on the monsoons.

Dr. Simpson's approval can scarcely extend to Mr. Pick's statement that "no great land masses are situated in the southern" hemisphere, for is there not the Antarctic continent, very potent in its influence on the air? The effect of oceanic circulation is passed by, and I am sorry that Mr. Pick has missed the interesting analogy between the upward gradient of temperature in the atmosphere and the downward gradient of temperature in the hydrosphere. The treatment of water vapour in the atmosphere is delightfully fresh and clear; the old confusion has passed away and the student who starts his study of meteorology with this little book is led straight into the heart of the subject.

To one who remembers the astonishment and incredulity with which Dr. John Aitken's discovery of nuclear condensation was greeted, it is quaint to see Mr. Pick's fresh mind jumping the event with "It was formerly thought that dust-particles formed the nuclei for condensation but——" and after all the new discovery is only that hygroscopic particles such as common salt are the efficient nuclei. Aitken classed salt-particles as "dust," and who can say that any particles in our atmosphere are not seasoned with salt?

To me the value of this short course is the proof it conveys that meteorology has attracted the rising men of science, not as a humdrum routine, but as a fascinating pursuit confidently expected to yield rich results. Already, as the admirable section on the upper air

and the brief but comprehensive account of weather forecasting show, the reward is being grasped.

Of the other publications before us, those dealing with the various codes for transmitting weather data are of interest only to the senders and receivers of telegraphic and radiographic reports, yet the mere fact that such elaborate systems of communication have become necessary shows the vastness of the recent strides in synoptic meteorology.

"The Observer's Handbook" is an old friend, inclining towards portliness now, and with an air of dignity consonant with its post-war price. The appendix of cloud-photographs by Mr. G. A. Clarke of Aberdeen, also issued separately, is helpful in defining the forms of cloud, and more so in showing how independent the clouds hold themselves of all hard and fast classifications. The prints of cirrus and allied forms showing the cloud in white on a blue ground are particularly effective.

The Handbook is ripening for complete revision and cannot yet be viewed as having reached a final form. It is still suggestive of the compiler's anxiety to justify the system of units recommended, and it remains rather over the head of the average observer, on whose faithful and patient routine the whole structure of weather study is based.

The new units which were suggested about 1908, and introduced by the Meteorological Office eight years ago, have had a less fair trial than the length of time they have been before the meteorological world suggests, as criticism on such matters was necessarily suspended during the war. I think that the substitution of the millimetre for the inch in rainfall measurement is well on its way; it is merely the substitution of one legal unit for another, and it makes for uniformity with other nations. The millibar, however, has not yet helped towards uniformity, although Commander Brooke-Smith, in his "Weather Forecasting ... for Seamen," says that "it will help towards obtaining uniformity if new barometers are graduated with this scale." I suppose that its future will depend largely on propaganda, like a new sect inspired by the ambition of unifying all the churches. Some observers will continue to look on it as simply a new linear measure. Once a rainfall observer, wishing to be up-to-date, ordered a rain-measuring glass to be graduated in millibars so as to be directly comparable with the barometer! The idea of freeing the measurement of atmospheric pressure from the gravity correction by using a unit based on acceleration instead of weight appeals powerfully to some minds. I think, however, that it will be apt to share the fate of the kilowatt in its competition with the horse-power, *i.e.* to be limited in its use to special lines of work. Messrs. Brunt and Durward, in their "Notes on Meteorological Corrections for the use of Gunners," use the old units, apparently as a matter of course, without apology.

So far as I can see from these publications, there is now a tendency to relax the boycott of the handy old Fahrenheit degree, thereby going back to the "absolute zero" of the snow-and-salt epoch. I have sometimes yearned for a scale starting at the "absolute zero" of the mercurial thermometer, that captivating temperature at which Fahrenheit and Centigrade thermometers read alike and below which mercury refuses to work. Can we look on the "absolute zero" of the air thermometer as absolutely fixed? May a lower temperature not be reached some day and a new way of estimating it be discovered? Think of the absoluteness of the old Daltonian atom. As a mere matter of nomenclature "absolute temperature" sounds unhappy in our days, when absolute time and absolute space are on the verge of becoming unfashionable. Be that as it may, I am glad that there is now less probability than there was once of temperatures reckoned from $-273°$ C. being harnessed to our English weather.

If I may conclude in a lighter vein I would refer to a misprint in one of the works under notice printed officially. Once on a time an official of a department, driven beyond discretion by the delays of another department, addressed a letter to the "Controller of H.M. Stationary Office," and was dealt with in a disciplinary manner. Times have changed, and now a waggish printer's imp has the audacity to speak disrespectfully of the isobars in these words—"anticyclones ... often remaining more or less stationery for several days."

HUGH ROBERT MILL.

The Constitution of Matter.

Der Aufbau der Materie: Drei Aufsätze über moderne Atomistik und Electronentheorie. Von Max Born. Zweite, verbesserte Auflage. Pp. vi+86. (Berlin: J. Springer, 1922.) 3*s*.

La Constitution de la matière. Par Prof. Max Born. Traduit par H. Bellenot. (Collection de monographies scientifiques étrangères, II.) Pp. iii+84. (Paris: A. Blanchard, 1922.) 6 francs.

THE most important part of Prof. Max Born's work is contained in the second and third of his essays, where he shows that it is possible to obtain approximate values for the heat of chemical union of the halogen elements with the alkali metals and with hydrogen from purely physical data. In collaboration with Landé he has calculated the repulsive force between the Na+ and Cl− ions in rock salt, which, combined with the ordinary Coulomb attractions and repulsions between these ions, accounts

for the measured compressibility, and finds that this force may be written $F=b/\delta^n$, where b and n are constants and δ is the distance between neighbouring ions of the same kind. For sodium chloride and other halogen-alkali compounds $n=9$. The law of force thus obtained is used to calculate the energy produced by the union of the ions to form the salt, which for one "Mol" is $U=545^3\sqrt{\rho/(\mu_+ + \mu_-)}$ kg. cal., where μ_+ is the atomic weight of the metal and μ_- that of the halogen. For absolute zero $U_{NaI}=158$, $U_{KI}=144$, when the ions are at rest in the position of equilibrium.

Nernst has shown that, if U is known, the chemical affinity *at any temperature* can be determined from purely physical considerations. These results can be checked by measuring the heat of solution of the salts, in solutions so dilute that dissociation is complete, and calculating the heat produced in such reactions as $NaCl+KI=NaI+KCl$. The values obtained were of the same order as those calculated by the above theory, but depend only on the *differences* between the values of U.

Another method of attacking the problem is to use Bohr's theory of atomic structure and radiation to find the work required to form ions from neutral atoms. Franck and Hertz have deduced that the energy of ionisation $I=h\nu_\infty$, where h is Planck's constant and ν_∞ is the limit of the series of absorption spectrum lines of the quiescent vapour. These workers have confirmed this theory by measuring the ionising potential which must be applied to a stream of electrons to produce a velocity just capable of ionising the vapour. They have thus found the energy of ionisation of a number of substances. Combining these values with values of the affinity for electrons of electro-negative atoms obtained by Franck, who used a method also based on Bohr's theory of the spectrum, the values of U can be calculated independently, and are within 12 per cent. of those obtained from the compressibility data.

Habers has studied metal crystals, on the assumption that the negative atoms in the Bragg space lattice are replaced by electrons. He finds for the alkali metals $n=2{\cdot}5$ to $3{\cdot}4$, copper $n=8{\cdot}0$, silver $n=9{\cdot}0$, in the expression for the repulsion. The heats of vaporisation calculated from these figures agree remarkably well with the observed values. The value of n must depend upon the distribution of the electrons in the ion.

The author seems perfectly justified in concluding his work in the following words: "If we survey the road we have travelled we see that, although it has not yet penetrated very far into the mighty kingdom of chemistry, it has reached a point from which we can observe, in the distance, the passes over which we shall have to travel if we wish to subject this kingdom to physical law."

Bauxite in Ayrshire.

Memoirs of the Geological Survey, Scotland. The Ayrshire Bauxitic Clay. By G. V. Wilson. Pp. vi+28. (Southampton: Ordnance Survey Office; London: E. Stanford, Ltd., 1922.) 1s. 6d. net.

WHILE deposits of bauxite, that is, of the aluminium hydroxides gibbsite and diaspore, are greatly in request as sources of aluminium, bauxitic clays are also of considerable value for the lining of high-temperature furnaces. It is well known that under tropical conditions of weathering, especially where the surface-waters are alkaline, rocks of very varied nature, containing aluminium silicates, yield bauxite rather than kaolin. Any ferruginous matter forms at the same time lateritic crusts. Laterite, indeed, as Sir Thomas Holland pointed out for India, is at times rich in aluminium hydroxide.

Bauxitic formations have thus come to be regarded as indications of climate in the past, and we now have the interesting discovery of bauxitic clays in strata of Millstone Grit age in Ayrshire. The lateritic nature of these Carboniferous beds was pointed out by Mr. John Smith in the Transactions of the Geological Society of Glasgow in 1893. The Geological Survey of Scotland, when recently remapping the area, collected samples for analysis and proved the presence of aluminium hydroxide. Mr. Wilson, in the memoir now published, defines a bauxitic clay (p. 6) as one that "contains more alumina than is necessary to supply the demands of the whole of the silica present for the formation of the kaolinite molecule." Silica present in the form of quartz sand is included in this definition, since such silica affects the value of a clay as a refractory material.

On p. 25 twelve analyses are given of the Ayrshire bauxitic clays. The most striking of these is that of the bed on the Saltcoats shore, which yields 47·57 per cent. of alumina and only 29·0 per cent. of silica. Titanium dioxide, a substance characteristically present, amounts, however, to 9·04 per cent., and the refractory quality of a kaolinite clay is said to be lowered by 5 per cent. and upwards. This effect is not so noticeable in clays with an excess of alumina. In the Ayrshire deposits, a large part of the material of inferior grade reaches a refractory quality of 30-31 on the Seger cone scale, while the Saltcoats shore material, despite its titanium-content, is recorded as over 35.

These bauxitic clays have been derived from basaltic lavas in the first instance, though in some cases the material has been transported. It is held that kaolinite was formed as the earliest product, and that a fairly pure aluminium hydroxide arose from this, sometimes with an oolitic structure. A recombination of the

silica set free occurred in some cases, a secondary kaolinite being formed. This association of kaolinite and bauxitic matter in the same series of deposits recalls observations made by the Geological Survey of Ireland on the Cainozoic beds of Co. Antrim (Mem. on the Interbasaltic Rocks, p. 51, 1912). In both areas, titanium dioxide is a prominent constituent of the clays; Mr. Wilson (p. 12) shows that it is present as rutile and anatase, less commonly as brookite, and sometimes in combination in sphene. He traces its origin to the augite of the basalts; in Ireland it has been attributed to the decay of ilmenite.

The new industry now developed in Ayrshire, in the manufacture both of refractory bricks and of alum, is a satisfactory result of the official researches here described. G. A. J. C.

Anderson Stuart: his Relation to Medicine and to the Empire.

Anderson Stuart, M.D., Physiologist, Teacher, Builder, Organiser, Citizen. By William Epps. Pp. xv+177. (Sydney, N.S.W.: Angus and Robertson, Ltd., 1922.)

THE career of Sir Thomas Peter Anderson Stuart has few parallels in medical or other annals. His student career in Edinburgh under Turner, Rutherford, and Lister was brilliant; his building and organisation of the Sydney school, and what they provoked, form a university romance of the first order. Dean for thirty-six years, he dominated medical history in Australia in a manner that few, if any, individuals will ever be able to imitate. During that period the number of students in medicine increased from four to nearly one thousand; and for this apotheosis of his department Anderson Stuart planned and built. Without any demerit to the brilliance of assistants in his faculty or to the capacity of men in other faculties of the University of Sydney, it is no exaggeration to state that that phenomenon was the offspring of Anderson Stuart's imagination and the fruition of his consummate scheming and effective individual manœuvre.

In this sphere his work was monumental. The standards set by Anderson Stuart in his school involved the emergence of such a university in Sydney as stands to-day—not merely a local inspiration, but the most prominent centre of Anglo-Saxon culture in the Southern Hemisphere. This achievement carries Stuart's work beyond the confines of institutional endeavour, and places it in the rank of empire-building.

For Australia, his work had a distinctive result in society-moulding, in that it was the initial step towards the quasi-aristocratic rank which the medical profession now enjoys in that country, and in that it foreshadowed and conditioned the elevated professional status which dentistry, veterinary medicine, nursing, midwifery, and massage are rapidly assuming in that continent.

Such are the more outstanding facts upon which Stuart's claims to remembrance will rest. As a physiologist and a man of science he was not distinguished, nor even as a teacher. Although he was a forceful lecturer, his words were selected for their rhetorical effect, and his lecture material was that of an earlier generation of physiologists. A claim to teaching ability must rest on more than rhetoric—it must rest upon the capacity to arouse the hearers to be *doers*; and doers in physiology as a result of Anderson Stuart's teaching are difficult to discover.

To present a man's autobiography with the force, frankness, and vividness that Mr. Epps has done, vindicates his claim that it was "a labour of love." He has carried out with nice selection a difficult piece of composition, which will always bring credit to himself and to the long list of subscribers. But Epps is not a Strachey. Although he has described many of Anderson Stuart's characteristics in the introduction, and although others crop out in the faithful narrative of events, the fearless character sketch is still unpenned. The achievement of a man is only explicable in terms of his character, and can be appreciated best when the record is frankest. Such incidents as the expectation of his name at the "top of the class list," and such self-appreciation as his own declaration that "I had the essentials of a good teacher born in me," reveal the character of Stuart more warmly and nakedly. A towering ambition and a Napoleonic will to tyrannic power, together with sufficient selfishness for the realisation of these twain—these very qualities are at one and the same time the key to his achievements, to the oppositions they evoked, and to the relentless manner of their crushing.

Anderson Stuart will always stand as a beacon-light and a landmark in the history of a university and a country which have a long future.

RAYMOND A. DART.

Our Bookshelf.

The Home of the Indo-Europeans. By Prof. H. H. Bender. Pp. 58. (Princeton: Princeton University Press; London: Oxford University Press, 1922.) 4s. 6d. net.

THE original home of the Indo-Europeans is a well-worn subject, and Prof. Bender has treated it generally on the lines of philology, familiar to readers of works like Schrader's "Prehistoric Antiquities of the Aryan Peoples." He suggests, but does not grapple with, the question whether there was an Indo-European

race, or merely an aggregate of tribes, possibly of varied physical characteristics, more or less closely united by a common tongue and a common culture. Anthropology and archæology may in time throw light, he suggests, on their habitat in the Stone Age, "although it will always be difficult to determine from the examination of a skull or a stone axe what language their owner spoke in life." Again, we have only grave furniture to guide us, and the consideration of broad or long skulls is of little help, because the cephalic index "is merely a ratio," and "among the living Chinese or in the Neolithic graves of Europe long skulls are nearly always found with short skulls, and *vice versa*."

Environment, again, affects the cephalic index, and the Scandinavians, supposed by some authorities to represent the primitive Indo-European type, "owe their long heads, not alone to race, but partially, at least, to hyperthyroidism and ultimately to the iodine of the seas near which they have lived, and from which they have obtained a considerable part of their food." The most novel point raised is that of the newly discovered Tocharian language in East Turkestan, a *centum* language, possibly introduced from the west, the home of languages of this type. Mainly on the evidence of philology the author reaches the conclusion, held by many scholars, that the primitive home of the Indo-Europeans was the great plain of Central and South-Eastern Europe, including the present Poland, Lithuania, Ukraine, and Russia south and west of the Volga. There is not much original matter in this little book, but the points are well put, and it will be useful as a guide to the study of a problem which has not yet been finally settled.

The Journal of the Institute of Metals. Vol. 27. Edited by G. Shaw Scott. Pp. viii+621. (London: The Institute of Metals, 1922.) 31*s.* 6*d.* net.

THE increase of research in non-ferrous metallurgy is so rapid that succeeding volumes of the Journal of the Institute of Metals show a rapid growth in size. Volume 27 contains some interesting papers on recrystallisation and grain growth. The paper by Mr. Adcock, containing a beautiful series of photographs illustrating recrystallisation in cupro-nickel, an alloy which proves very suitable for the purpose of this study, will be of material assistance in advancing the subject, which has been studied with such good results by Carpenter and Elam. Major Smithells' paper on grain growth in tungsten filaments makes use of the hypothesis of varying vapour pressure. Condenser tubes are considered from two points of view, the experience of the Corrosion Committee being utilised as a basis for recommendations as to their care in practice, while a second paper from the Research Department at Woolwich deals with the prevention of season cracking by the simple process of removing stress by low temperature annealing. The revision of the alloys of aluminium and zinc clears up some difficult points in the behaviour of this curious system, one of the most interesting in respect of its changes in concentration of solid solution with temperature. Several other papers deal with questions of practical importance, and the volume contains a very large number of abstracts of work published elsewhere.

Arab Medicine and Surgery: A Study of the Healing Art in Algeria. By M. W. Hilton-Simpson. Pp. viii+96+8 plates. (London: Oxford University Press, 1922.) 10*s.* 6*d.* net.

IN this volume Mr. Hilton-Simpson describes the medical and surgical methods of the Shawía of the Aurès Massif of Algeria. His record is the result of careful inquiry pursued in the course of a number of visits to the country, and possesses a peculiar value in that it deals with practices which must inevitably disappear before the advance of civilisation. Although some of the treatment prescribed by Shawía medicine is derived "from the sorcerer's defensive armour against Jenun," the demons or spirits which cause disease, medical practice is not here synonymous with magic, as among most primitive peoples. The medical practitioner is regularly apprenticed, usually to a member of his own family. The medical treatment would appear to be derived from the medicine of the medieval Arabs. The origin of their surgery is more obscure, and it has been suggested, on account of the primitive character of their instruments and the prevalence of the operation for trepanning, in which they take much pride and show much skill, that it may possibly go back so far as the Neolithic age. The trepanning operation is usually successful, a fact which is due perhaps as much to the remarkable vitality of the people as to the skill of the surgeon.

A Naturalist's Calendar, kept at Swaffham Bulbeck, Cambridgeshire. By L. Blomefield. Second edition, edited by Sir Francis Darwin. Pp. xviii+84. (Cambridge: At the University Press, 1922.) 3*s.* 6*d.* net.

THE Cambridge University Press was well advised in adopting Sir Francis Darwin's suggestion to republish this Calendar. Lists such as those compiled by Blomefield not only assist the amateur naturalist, but are of real value as contributions to the science of phenology. A collection of such Calendars embodying the notes of some of the scores of observers scattered over the British Isles, and based on a consecutive series of years, would probably add not a little, in the hands of a central receiver, to our knowledge of the movements of birds, the awakening of vegetation, and other phenomena dependent upon the seasons.

Woodland Creatures: Being some Wild Life Studies. By Frances Pitt. Pp. 255. (London: G. Allen and Unwin, Ltd., 1922.) 12*s.* 6*d.* net.

"STUDY any animal, even the most common, carefully, and you will find out something that has hitherto escaped notice." Repeatedly did this sentence spring to mind as we read the pages of this charmingly written and beautifully illustrated book. The author, whether writing of the furred or the feathered creatures of our woodlands—of badgers, foxes, dormice, rabbits and squirrels, or of woodpecker, bullfinch, kestrel, sparrowhawk, owl, magpie and jay,—tells us something of habits or of adaptation of structure to habit that we have not met elsewhere; and not infrequently has shrewd criticism to offer on plausible theories of armchair origin. Her photographic illustrations bear comparison with the very best.

Palæontology and Archaic Fishes.

It is now a good many years since I first decided to devote myself to the study of vertebrate morphology. I was attracted to this study through feeling in the old days at Cambridge that the position of comparative neglect into which this science had fallen was the fault, not of the subject itself, but rather of that band of enthusiasts who, carried away by the inspiration of Darwin, and setting to work at the building of the new morphology, took in their haste but little heed that the foundations upon which they built were adequate either in extent or in sound workmanship. As regards the former, an important gap in the foundations was glaringly visible in the region occupied by these two exceedingly archaic subdivisions of the Vertebrata—the Crossopterygii and the Dipnoi. In particular, nothing whatever was known regarding the early developmental stages of any crossopterygian or of either of the two lung-fish which seemed nearest to the evolutionary stem of the terrestrial vertebrates. It was the recognition of the importance of this gap in the foundations of vertebrate morphology that, above all, influenced me in taking the decision to do what I could towards making the gap less extensive. Seeing that so much of my research work has been concerned with the two groups I have indicated, I may perhaps be regarded as justified in having a special interest in them and their relation to the general problems of vertebrate morphology.

I am in consequence particularly interested to find in the newly published Proceedings of the Linnean Society the presidential address of Dr. Smith Woodward entitled "Observations on Crossopterygian and Arthrodiran Fishes." In view of the president's position as the official head of British palæontology, and still more in view of his pre-eminent position as an investigator of the palæontology of the lower vertebrates, his words will carry great weight where he is dealing with palæontological fact. In the course of his address, however, he comes into touch with some of the broader questions of vertebrate morphology, the answers to which, if they are to be trustworthy, must necessarily be based upon the judicial consideration of all the evidence available, and not merely of that which is constituted by the data regarding skeletal structure afforded by palæontology. It is, I think, particularly necessary to remind the younger generation of workers, to whom will fall the task of restoring morphology to its proper position in biological science, that as regards several of the questions dealt with by Dr. Smith Woodward, due heed must be given to witnesses other than palæontological.

It would not, for example, be gathered from the address in question that we do not all accept Dollo's view that the modern lung-fish have "abandoned the fusiform shape which is adapted for free-swimming life, and have become (secondarily) more or less eel-shaped in adaptation to a wriggling and grovelling existence."

There is no general characteristic of the Vertebrata more fundamental than the fact that during early stages in their development their muscular system consists of segmentally arranged blocks of longitudinally-running fibres along each side of the body. There is no escape from the physiological implication that this peculiar arrangement of the muscular system has for its function the production of movements of lateral flexure. To some of us, the further conclusion appears to be equally inevitable that the vertebrates in general were in early stages of their evolution "more or less eel-shaped in adaptation to a wriggling and grovelling existence."

The view may of course be held that, even admitting that the primitive vertebrates were elongated in form, yet the ancestors of existing Dipnoi were, for a time during their evolutionary history, fusiform—just as was undoubtedly the case with the ancestors of the eel-shaped teleostean fishes.

Whichever view is taken as to the fusiform ancestral stage of the Dipnoi—whether primitive or merely intercalated—I regard the evidence in the way of known facts as quite inadequate to form the basis of any such idea. This evidence is palæontological in its nature. Stated shortly and crudely, it is constituted by the fact that the palæozoic dipnoans with which we are acquainted up to the present are on the whole fusiform, while the modern dipnoans are elongated in form.

Personally, I take the view that the vertebrates, during the prolonged early phases of their evolutionary history before they evolved into creatures highly specialised, on one hand, for a purely swimming habit—like the modern fish—or, on the other, for a terrestrial existence as are the modern tetrapods, were actually, in all probability, creatures of elongated form of body which "wriggled and grovelled" in a swampy environment. Further, I believe that such conditions are highly unfavourable (1) to existence in crowds or shoals, and (2) to that rapid enclosure in preservative silt or other deposit which is essential to their persistence as fossils. Consequently I should attach very little weight to the fact that the specimens known to us as fossils of the palæozoic dipnoans happen to have fusiform bodies. As a matter of fact, I regard the fusiform body just as I regard the divided-up median fin and the heterocercal tail (or its further development the homocercal tail), as marks of the efficient swimmer. They are characteristics which I should expect to find in the majority of species in any group of fish during its period of maximum prosperity, when it reached the highest degree of adaptation to a purely swimming existence.

Dr. Smith Woodward mentions the failure up to the present to discover fossil links between the paired fin of the crossopterygian and the leg of the terrestrial vertebrate. I suppose I am still in the position of being the only investigator of the evolutionary history of the vertebrate limb who has had at his disposal embryological material of Polypterus and of all the three genera of lung-fish in addition to that of elasmobranchs and amphibians. It may be well, then, to state that my own work, together with a careful consideration of the work of others, palæontologists, anatomists, and embryologists, leaves no doubt in my mind that the reasonable view to take is that which regards the paired fin (of whatever type—archipterygial, crossopterygial, or actinopterygial) on one hand, and the pentadactyle leg on the other, as being limbs specialised for different types of movement, neither of which has evolved out of the other, but each of which has evolved out of an ancestral, more or less styliform, type of limb.

There is another point to which it seems desirable to refer, namely, the use of group names based on our knowledge of existing animals in discussions on palæontology. The natural classification of animals is of course a concise method of summing up their

morphology, *i.e.* their genetic relationships as expressed by their structure. In working out these relationships, as every morphologist knows, it is essential to have due regard to structure as a whole, collecting and weighing the evidence afforded by all the various organ systems of the body. The group name Dipnoi, or Amphibia, or Reptilia, or Aves, or Mammalia, connotes in each case a particular assemblage of structural characteristics relating to the entire structure of the body.

Now it is particularly desirable to bear in mind that when an extinct animal is allocated to one of the larger classificatory groups, this is done as a rule on no more sure basis than a knowledge—often a very imperfect knowledge—of the inorganic portions of its skeletal system, and consequently such allocation is, as regards the probability of its being correct, on a totally different footing from the assignment of a modern animal to its taxonomic group after full consideration of its whole structure. It is quite impossible for any one to say whether a palæozoic creature now included in the group Dipnoi or Crossopterygii would, or would not, have this inclusion justified were we acquainted with its general structure apart from the skeleton. The same consideration indicates to us how vain were the old controversies as to whether the ancestor of the group Mammalia was an amphibian or a reptile. Even had we before us the undoubted skeleton of that ancestor in perfect condition, we should still require to know about its soft parts—its skin, its heart, its main blood vessels, its brain, its urino-genital organs, its embryonic membranes, and so on—before we should be justified in concluding definitely in which, if either, of the two groups named it should really be included.

Some Interesting Tracks of Alpha Particles in Gases.

SELECTED photographs taken from about ten thousand exposures show a number of types of alpha ray tracks, some of which have been described before and some have not. Fig. 1 gives a track in which

FIG. 1.

it is apparent that the alpha particle hits the nucleus of an oxygen or nitrogen atom. The nucleus is projected forward at a very high speed, while the alpha particle is reflected backward at a sharp angle. In Fig. 2 the track is an almost straight line with a branch which goes off at an angle of about 8°. In some instances the branch is at an angle as great as 50° with the straight track. An example of this is given in Fig. 3, though in the plane of the photograph the angle is only 40°. In some instances another type of track is given, in which one of the

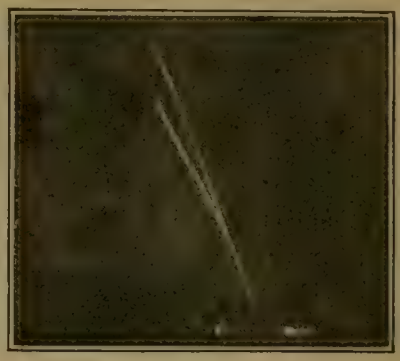

FIG. 2.

branches is very short, the other very long. It is not unlikely that some of the longest tracks are due to hydrogen nuclei. A discussion of the tracks will be published very soon in one of the physical journals. All the photographs were taken by the Shimizu-

FIG. 3.

Wilson method, by means of which many more photographs showing views at right angles will soon be taken.

The Age and Area Hypothesis.

IN a paper by the late Prof. D. P. Penhallow, of McGill University, Montreal, entitled "A Review of Canadian Botany from the First Settlement of New France to the Nineteenth Century, Part I." (Proceedings and Transactions of the Royal Society of Canada for 1887, volume 5, section 4, pp. 45-61, 1888), the following passage occurs:

"But Michaux appears to have attached a much wider importance to his prospective work, and to have regarded it more from a scientific point of view, since he had already conceived the idea that the distribution of the trees of America should be studied, and that it would be possible to ascertain their original centres of distribution through careful observation of their dimensions and predominance in different parts of the country. It was the elaboration of this idea that largely led him in so many directions, and over so wide a range of territory" (D. P. Penhallow, Proc. and Trans. Roy. Soc. Can., 1887, 5, sect. 4, pp. 55-56, 1888).

Apparently Michaux was of the same way of thinking in reference to the Origin of Species as Dr. Willis. J. ADAMS.

Central Experimental Farm,
Ottawa, December 18.

THIS reference is of great interest. As I have shown in the Introduction to my recent book upon "Age and Area," both Lyell and Hooker had conceived the ideas which I have elaborated. The incoming of the Darwinian theory of evolution, however, with its novel conception of universal gradual change, diverted effort from the lines that it was beginning to follow, and to which it shows signs of returning, with the increasing recognition of the fact that gradual change is not possible in the case of most characters. JOHN C. WILLIS.

Zoological Nomenclature : Musca and Calliphora.

IN accordance with the rules of the International Zoological Congress, the attention of the zoological profession is invited to the fact that Dr. L. O. Howard, W. Dwight Pierce, and twenty-one other professional zoologists have requested the International Commission on Zoological Nomenclature to exercise its plenary power in the case of the Linnæan genus Musca, 1758, and, under suspension of the rules, to declare *M. domestica* as type of this genus; also, under suspension of the rules, to validate Calliphora, Desvoidy, 1830, with *C. vomitoria* as type.

The request is based on the grounds of practical utility, and an almost unbroken history of consistent usage since 1758 in the case of Musca, and since 1830 in the case of Calliphora. It is claimed that a strict application of the rules will produce greater confusion than uniformity.

According to the premises at present before the Commission, if the rules are strictly applied, the generic name of Musca would take either *M. cæsar* or *M. vomitoria* as type, and the species *M. domestica* would be cited either in Conostoma, 1801 [?] (type *Ascaris conostoma* = larva of *M. domestica*), or in Conosoma, 1802 (type *Ascaris conosoma* = larva of *M. domestica*), or in Promusca, 1915 (type *M. domestica*), thus resulting in a very regrettable change in the nomenclature of the species in question as almost universally used in entomological, zoological, medical, epidemiological, and veterinary literature.

The secretary of the Commission invites any person interested in these cases of nomenclature to communicate his opinion on the subject as soon as possible. On account of delay caused by the war, the final vote of the Commission will not be taken until about January 1, 1924. C. W. STILES
(Secretary to Commission).

Tesla Spectra and the Fraunhofer Effect in Complex Compounds.

IN conjunction with Mr. W. H. McVicker, we have begun an investigation of the spectra emitted by the vapours of compounds when subjected to waves from a Tesla transformer passing between two glass-coated electrodes. For the sake of clarity, these spectra may be termed electro-luminescence spectra.

Among the substances examined by us was benzene. At ordinary pressure and at the boiling-point, the vapour of benzene emits only a fragmentary spectrum which seems to be built up from portions of the carbon spectrum, only the strongest bands making their appearance. On reducing the pressure of the vapour, an extremely regular spectrum is emitted by benzene; a very regular set of band-groups, each of which has the same general internal structure as the others. Six of these band-groups lie between $\nu = 3194$ and $\nu = 3752$; while traces of yet another band-group were observed in the region beyond 3194. Beyond 3765, the absorptive power of the vapour itself cuts off part of what is evidently another set of band-groups.

Each of the band-groups has the following structure: four strong bands, each accompanied by a weaker band; then two broader and weaker bands, which may possibly be produced by the fusion of the strong and weak companions of a doublet.

The whole spectrum shows an extraordinary regularity. There are no air-lines or spark spectra traceable throughout its extent; nor are there any lines visible on the parts of the plate unaffected by the luminescence spectrum. The following figures represent the wave-numbers of the four strong bands in each group:

Group A.	B.	C.	D.	E.*	F*.
3752	3652	3554	3454	3357	3257
3736	3636	3537	3438	3339	3242
3717	3618	3521	3422	3322	3229
3703	3602	3504	3405	3308	3211

For the band-groups marked with an asterisk, the readings on the plate were difficult—the bands being diffuse—and the figures are probably not exact.

The whole of the bands in the electro-luminescence spectrum appear to be directly related to each other; their wave-numbers are calculable from the following formula:

$$\nu = 98{\cdot}712n - \frac{98{\cdot}712m}{6},$$

where n is successively equal to 33, 34, 35 . . . and m is successively 0, 1, 2. . . .

The electro-luminescence spectrum presents especial interest when it is compared with the fluorescence and absorption spectra of benzene. Hartley (Phil. Trans., 1908, 208, 519) and Grebe (*Zeit. wiss. Phot.*, 1905, 3, 363) found that the change from benzene vapour to a solution of benzene in alcohol produced a shift of 10-20 units in the position of the absorption bands towards the less refrangible rays. If the same shift be assumed to occur in the case of fluorescence, then it appears that the full fluorescence spectrum of benzene corresponds, band for band, with a part of the luminescence spectrum, as the following figures show:

Electro-luminescence bands . .	$\nu = 3454$	3554	3652	3752
Fluorescence bands . . .	$\nu + 19 = 3454$	3556	3650	3752

An even more surprising result is obtained by comparing the electro-luminescence and absorption spectra of benzene vapour. Hartley (*loc. cit.* 484) divides the absorption bands into four series. When his least refrangible bands are compared with our most refrangible set, the coincidence between the two is most remarkable. For the sake of brevity, only the first strong series is given here:

Absorption bands .	= 3650	3683	3700	3716	3734	3749-52	3761
Luminescence bands .	= 3652	3686	3703	3717	3736	3752	3765

Thus, if an obvious constant difference of 2 units between our scale-readings and those of Hartley be assumed, all these bands coincide within our experimental error.

This appears to establish that parts at least of the benzene absorption spectrum are replaced by luminous bands in the electro-luminescence emission spectrum, just as the dark Fraunhofer sodium line in the solar spectrum corresponds to the D-line in the emission spectrum of sodium. In other words,

the Fraunhofer effect has now been established in the case of the spectrum of an organic compound of complex structure.

A more detailed account of this work will be published almost immediately. We wish to reserve this particular group of spectra for our own investigation, as we have already planned and in part carried out a connected series of investigations upon it, which we wish to complete before venturing upon the theory of the matter. We hope also to investigate the behaviour of solutions under the influence of the Tesla discharge.

Distribution of the Organ-Pipe Diatom (*Bacillaria paradoxa*).

IN connexion with the interesting question raised by Mr. F. Chapman in NATURE of January 6, p. 15, as to the peculiar movements of *Bacillaria paradoxa* being due to osmotic pressure, I am writing to say that all the specimens observed by Mr. H. Weaver and myself that were gathered from the Staffordshire and Worcestershire Canal at Stourport and from ponds at Wilden and Hartlebury (see NATURE, vol. 108, p. 163) were very active and so continued during the period we kept them under observation (about a week in each case). The water in this canal and in these ponds is some eighty miles removed from the sea. It is quite fresh and not at all brackish.

Experiments on Hardness and Penetration.

As a student of colloidal chemistry I was much interested in the results of the experiments on the clay-water systems by Mr. A. S. E. Ackermann (NATURE, January 6, p. 17), showing that there was a continuous penetration of the systems by a heavy object when its pressure exceeded a certain critical value referred to as the "pressure of fluidity."

The phenomenon has been observed in many colloidal systems and also with the coarser systems such as paints, thick oils, etc. Bingham found zero fluidity or infinite viscosity with 4 per cent. china clay or 5·5 per cent. of graphite. E. Hatschek, investigating aqueous solutions of gelatine, showed that the viscosity varied with the rate of shear, and a similar conclusion was reached by Hatschek and Humphrey, working with systems of sifted rice particles in toluene-carbon tetrachloride. In general, at the lower rates of shear the viscosity is abnormally high and even infinite if the system be coarse-textured.

With the Stormer type of viscometer the curve relating the number of revolutions per minute of the cylinder rotating in a coarse system such as a paint or grease, with the load rotating it, is curvilinear and does not pass through the origin.

The minimum load required to start rotation, apart from that to overcome the friction of the apparatus, would correspond to the "yield point" obtained by the use of Bingham and Green's plastometer, or the "pressure of fluidity" by Mr. Ackermann.

It is evident that the viscosity of these systems has lost its usual significance since it is a variable function and any value obtained by any one method is empirical. This would apply to the value given by Mr. Ackermann for the viscosity of lead in the solid state.

Another interesting phenomenon in this connexion is that the rate of penetration by the object gradually decreases and eventually ceases; thus a steel ball remains suspended in a well-mixed paint after a fall of some distance. With some oils, a falling sphere cuts a path through the liquid, so that the apparent viscosity decreases with each determination by the falling sphere method.

E. MARDLES.

2 Hillfield Villas, Union Street,
Farnborough, January 9.

IT is with great interest that I read Mr. Ackermann's letter in NATURE of January 6, p. 17, with regard to the penetration of clay and lead by a loaded disc. The manuscript of a paper intended for the next meeting of the Iron and Steel Institute is now complete. The work deals with several of the deductions to be made from my formula for Brinell hardness (NATURE, December 9, vol. 110, p. 773).

While clay has not been examined, tests have been carried out on pitch and plasticine. Meyer's formula appears to be true for these two materials.

A New Gregarine Parasite of Leptoplana.

MR. SAM SETNA, who is working under my supervision on the Polycystid Gregarines, has just found specimens of a Cephaline Gregarine infesting a specimen of *Leptoplana sp.* recently obtained from the Marine Biological Laboratory at Plymouth. This Gregarine seems to be rather a rare parasite of Leptoplana, as no Gregarine has been described before from Leptoplana, according to lists given by Minchin (1903) and Watson (1916), or in literature published since. Indeed, extraordinarily few Sporozoa have been found from the Platyhelminthes as a whole. The find is all the more remarkable as Leptoplana is so commonly used as a type animal. Only a single specimen was found to be infected, and other specimens in the same tube that have been examined do not show the infection.

In the sections of the infected worm, a number of individuals of the Gregarine have been found in the parenchyma of its body. The trophozoite is solitary and quite large in size, measuring from 103 μ to 168 μ in length. The protomerite is quite distinctly marked off from the deutomerite. Only one young individual has been found showing the epimerite. The latter is large, hemispherical, and simple. The nucleus is large and rounded and measures 19 μ to 23 μ in diameter, and exhibits the characteristic Gregarine structure, with a slightly eccentrically placed karyosome and a number of chromatin particles disposed round it.

Unfortunately, no other stages of the life-history have been encountered, and it is consequently impossible to refer the parasite to any particular genus.

Discovery of the Use of Phosphates as Fertilisers.

IN view of the interest attaching to the so-called artificial fertilisers, it may be worth recording that the idea of the possibility of utilising raw mineral phosphates as phosphatic fertiliser is to be found in the current agricultural publications some years before 1840, the date usually regarded as that of the first serious record.

In 1842 Lawes took out his patent for the manufacture of superphosphate. In a question of infringe-

ment that arose later he showed that his application for a patent was the result of work at Rothamsted with bones and mineral phosphates from 1839, and with bone dust from 1843. Liebig had suggested phosphatic manure in a report to the British Association in 1840.

But in May 1837 an unnamed correspondent of the *Farmers' Magazine* (2nd series), writing on the difficulty and expense of obtaining bone dust in the required quantities, proposed the making of a "fictitious bone dust by impregnating lime with phosphoric acid." Another correspondent in answer asserted (May 1837) that there was no cheaper way of getting phosphorus than by burning bones, adding, however, "phosphate of lime if it could be found so as to be available to the farmer, would be invaluable. Whether it exists in England I know not, but in Spain there are entire mountains of it; it is compounded of phosphoric acid 41 parts, lime 59"; showing an earlier appreciation in England of the fertilising possibilities of Spanish phosphorites than is generally realised.

Whether or not Lawes had read these letters we do not know, but they form an interesting foreshadowing of the great work he began two years later.

Soil Reaction, Water Snails, and Liver Flukes.

MAY I be allowed to add a few words to the discussion on *Limnæa peregra* and the liver rot of sheep, etc. First with regard to outbreaks of the disease following the application of lime. During a considerable experience of Mid and North Wales I have had a number of such cases brought to my notice by farmers (in one case basic slag had been used). In all cases the dressings had been applied to rough wet pastures of the "sour" type, which are not grazed closely by stock. In parts of these fields *L. truncatula* was present, but, owing to light grazing of the abundant herbage, the encysted cercariæ had presumably not been ingested. Following an application of lime, a "sweetening" or improvement of the pasturage leads to closer grazing and a more or less intense infection of the stock. This, at any rate, is my opinion following the investigation of actual cases.

Secondly, as to the distribution of the two species of Limnæa (in the same regions). Both are abundant, and although they may occur together now and again, it is usual for *L. peregra* to frequent the softer muds and *L. truncatula* the firmer substrata. For example, if a small streamlet be followed, *truncatula* will often be found in its upper and *peregra* in its lower (and more muddy) portions. In a wide ditch, *truncatula* may occupy the margins and *peregra* the soft central portion. These habitat differences are probably due to the relative size and expanse of foot. While working on the bionomics of *truncatula* I made some notes on *peregra* also; these were incorporated in a paper published in *Parasitology*, x., No. 2, December 1917.

With regard to *peregra* acting as an intermediate host for *Fasciola hepatica*, I have on several occasions obtained cercariæ from that species which I cannot distinguish from that of *F. hepatica* (*Cercaria fasciolæ hepaticæ*, Thomas). This, however, is not a common occurrence in my experience, although I have examined numerous samples of *peregra*. The last two cases were (*a*) from ill-drained fields, near Llanwnda, Carnarvonshire, elevation about 100 feet; (*b*) on the mountains near Bethesda, elevation more than 1000 feet. In both instances liver rot had occurred. In the first *truncatula* was present also; in the second only *peregra* could be found. C. L. WALTON.

The Silent Zone in Explosion Sound-Areas.

IN the recent interesting article on the Oldebroek explosion, it is stated (NATURE, January 6, p. 33) that in no case has it been found that the nearer margin of the outer sound-area lies at so short a distance as 114 km. from the source. When the minute-guns were fired at Spithead during Queen Victoria's funeral procession on February 1, 1901, there was a clearly marked silent zone, and the nearest point of the outer sound-area was 80 km. from the flagship. In this case the sounds were easily recognised, as they recurred at regular intervals (*Knowledge*, vol. 24, 1901, pp. 124-25; *Science Progress*, vol. 14, 1920, pp. 625-26). In the sound-area of one of the Asama-yama explosions (December 25, 1910) the corresponding distance was about 87 km. (Bull. Imp. Earthq. Inves. Com., vol. 6, 1912, pp. 61-63 and plate 18). These figures have an important bearing on the origin of the silent zone.

Time Relations in a Dream.

IT is commonly believed that a dream which appears to be of long duration lasts in reality for a short time only. Since precise knowledge on the point is difficult to get, the following observations may be of interest. Having fallen asleep again, after being called a few mornings ago, I dreamt I was visiting a strange laboratory. On entering I was aware of a deafening hammering noise which rendered conversation impossible. My host took me to another room, where the noise was inaudible, but on returning to the first room it continued, the blows being at about the same interval. I then noticed, what I had not seen before, some one striking a pipe in a shaft in the wall, but I reflected that the force used seemed quite insufficient to produce the sound heard.

On awaking suddenly I connected the sound with the chipping of a stone-mason at work on the war memorial across the road. Remembering Mr. J. Barcroft's letter to NATURE (1919, vol. 104, p. 154), I timed the chipping blows. They were from 26-34 per 10 seconds, averaging 3 per second. Going over the dream it seemed that the loud sounding blows, which produced a continuous reverberation, were about 15 or 16 per 10 seconds; thus the time in the dream proceeded at about—or possibly slightly less than—twice the normal rate.

Both before and after the cessation in the dream—corresponding probably to one of the mason's pauses—the rate was the same. In this respect the experience differs from Dr. Barcroft's, for his clock ticking four to the second appeared to give a five-second interval, namely a twentyfold exaggeration; this, later in the dream, was reduced to a fourfold exaggeration. The noise of which I was conscious in the dream appeared to go on before the interval for about a minute and after it for two or three, with about a minute between. The duration of the dream appears accordingly to have been about two minutes or slightly longer. The loudness of the noise, as it was experienced in the dream, is remarkable in view of the actual loudness. The note was also far more metallic. W. R. G. ATKINS.

The Disappearing Gap in the Spectrum.[1]

By Prof. O. W. RICHARDSON, F.R.S.

I.

THE Royal Institution seems a peculiarly fit place to deliver lectures on this subject, because it was while he was professor here 120 years ago that Thomas Young, the great advocate of the wave theory of light, showed how to estimate the wave-lengths of the different parts of the spectrum, and by so doing laid the foundations of spectroscopy as a quantitative science. His determinations of the wave-lengths in the visible spectrum were based on Newton's observations of the colours of thin plates. He also explained the principle of the diffraction grating, and by experiments based on the method of Newton's rings he showed that the actinic or ultra-violet rays had shorter wave-lengths than those in the visible. The wave-lengths of the visible spectrum extend from a little below 4000 to a little above 7000 Ångström [2] units, or, roughly, over about an octave. On the infra-red side we have, first, the invisible rays, often referred to as radiant heat, which contain the major part of the energy in the solar spectrum and a greater proportion still of the energy radiated from bodies at a lower temperature. Beyond these we have the long electromagnetic waves of the type we are familiar with in wireless telegraphy. This side of the spectrum extends to waves of infinite length or of zero frequency.

The gap in which we are interested is on the other side of the visible spectrum in the region of waves of shorter length or higher frequency. In 1801 Ritter showed that there was something beyond the violet end of the visible spectrum which blackened chloride of silver. In other words, there are ultra-violet rays which, as we should now say, are capable of photochemical and photographic action. They also have other properties—they excite fluorescence in substances such as uranium glass, and they liberate electrons from the surface of a metal plate. They are, however, not very freely transmitted by glass; or, to put the matter more precisely, the ultra-violet spectrum which is transmitted by a glass prism spectroscope, does not extend very far beyond the visible limit. By substituting quartz for glass in the spectroscope, and by other improvements, Stokes was able to make a very notable extension and to carry the limit to beyond 2000 Å. This made the ultra-violet extend over more than an octave, and measured in that way its extent had become greater than the whole of the visible spectrum.

The limit to further extension was now found to be set by two things—(1) the absorption of quartz, which becomes fatal about 1850 Å, and (2) the absorption of air, which also becomes prohibitive in the same neighbourhood. These difficulties were faced and overcome up to a certain point by Schumann, who constructed a fluorite spectroscope which he could operate, with all its adjustments, in an evacuated chamber. In this way he succeeded in pushing to the limit of transparency of fluorite, which is in the neighbourhood of 1250 Å with good specimens.

The limit to further development was set, and the possible lines of advance narrowed down, by a very remarkable and important property of the radiation in this part of the spectrum, to wit, that every known material substance is practically completely opaque to it. I believe this high absorbability of the radiation to be due to the combined influence of two facts—(1) that the quantum of this radiation exceeds the ionisation or radiation quantum of every atom, and (2) it does not exceed it by so much that there is any considerable chance of the radiation getting past the atom which, as it were, is set to trap it. We have precise evidence that absorption sets in as soon as, but not earlier than, the frequency at which the quantum of the impinging radiation exceeds the ionisation or radiation quantum of the atom. We also have considerable evidence, both theoretical and experimental, that the chance of absorption is greater when the two frequencies are comparable than when they are widely divergent in magnitude. These considerations exclude completely any apparatus of the type of the prism spectroscope, in which the radiation passes through considerable portions of matter such as the materials of the prisms and lenses.

There is one spectroscopic apparatus which is free from this difficulty, namely, the concave grating invented by Rowland. In this device, if the slit, the grating, and the screen or photographic plate are all arranged to lie on a circle perpendicular to the rulings having a diameter equal to the radius of curvature of the grating, the spectrum is sharply focussed without using any lenses. The adaptation of the concave grating for use in this part of the spectrum is due to Lyman, whose vacuum grating spectroscope has only begun to bear the fruit which we may reasonably hope ultimately to gather from it. With this instrument, which I shall refer to more fully later, by 1913 Lyman had measured the wave-lengths of a large number of lines between the limits reached by Stokes (quartz) and Schumann (fluorite), and had also extended the known spectrum to the neighbourhood of 900 Å, which is the short wave limit of the most fundamental hydrogen atom spectrum series, now known as the Lyman series.

At that time, then, the spectrum was known to be continuous from wave-length infinity to wave-length 900 Å, or in terms of frequency from zero to $3{\cdot}333 \times 10^{15}$ vibrations per second. It was also known that we had in the X-rays and the γ-rays from radioactive substances rays of still higher frequency and shorter wave-length. Prior to the discovery of the crystal diffraction phenomena the wave-lengths of X-rays had been ascertained roughly by photoelectric methods—a fact which seems generally to have been forgotten—but by 1913 they had been measured accurately by the Braggs and Moseley with the crystal spectrometer. Moseley's measurements include such rays as the K-rays of aluminium, which are in the neighbourhood of 8 Å, and this was the longest X-ray wave then known. There was thus a gap from 8 Å to 900 Å, or about seven octaves. This is the gap with which I propose to deal.

I do not know that any systematic or very thorough attempt has been made to push the measurements of

[1] Substance of lectures delivered at the Royal Institution on May 13 and 20 1922.

[2] 1 Ångström unit (Å) = 10^{-8} cm.

X-ray wave-lengths so far as possible in the long wave direction by crystal methods, but it is evident that there must be a limit, and it is possible that this limit has almost been attained, for in spite of the great improvement in technique and the extraordinary

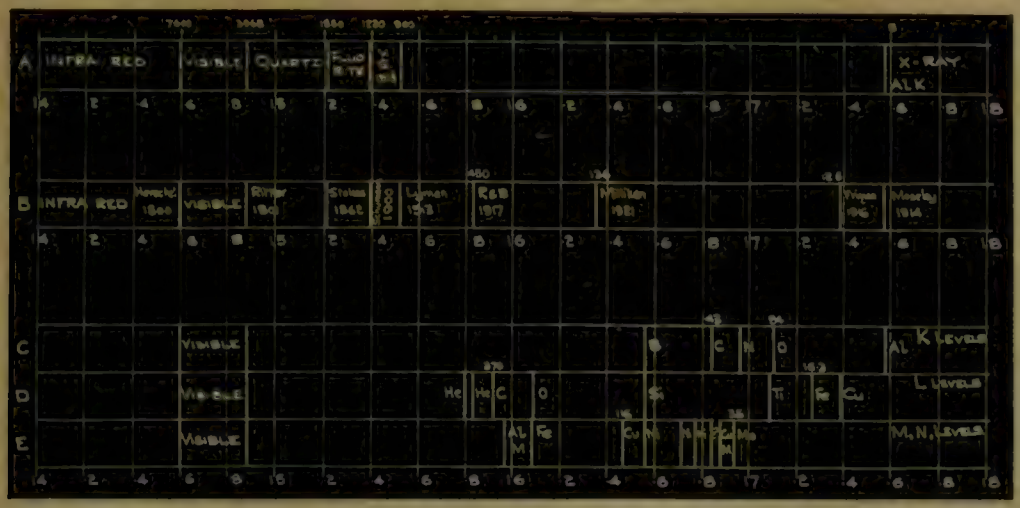

FIG. 1.

activity in this line of work since Moseley's measurements in 1913, the longest wave-length I have been able to find recorded as measured is the zinc L_{α_1} line given by Friman as 12·346 Å. This represents but half an octave out of the seven octaves between the limits left by Lyman and by Moseley.

The failure of crystal methods is due to two causes. The distance between the centres of the atoms in solids is of the order of an Ångström unit, so that at 12 Å the waves are already much longer than the distance between the reflecting planes which form the grating elements. (For the crystals rock-salt and calcite, with which most of the accurate measurements have been carried out, these distances are $2{\cdot}184 \times 10^{-8}$ and $3{\cdot}028 \times 10^{-8}$ cm. respectively.) The other difficulty arises from the intense absorbability of these soft X-rays by practically everything, a phenomenon that we have already witnessed in the radiation on the other side of the gap. Sir William Bragg has recently been investigating some organic crystals which have grating spaces very much farther apart than rock-salt and calcite, and it may be that in employing such crystals in an evacuated system we have a way of making considerable advances into the gap from the high-frequency end by the X-ray crystal diffraction methods. It would seem that in Moseley's original apparatus we have an arrangement which could be rather easily developed for this purpose. Another advantage of these crystals is the possibility that they may not absorb the rays so very intensely, as the only known substances which have appreciable transparency in this region are organic compounds or mixtures of them, such as celluloid.

Returning to the position about 1913, this is conveniently exhibited by diagram A of Fig. 1, in which the various spectral limits are marked against an even scale proportional to the logarithms of the corresponding frequencies. These are shown by the numbers on the base line, the numbers given at the top being corresponding wave-lengths in Ångström units. It will be seen that this representation is similar to that of the keyboard of a piano, equal horizontal spacings corresponding everywhere to an equal number of octaves. The great width of the gap between the X-ray and ultra-violet limits is very apparent.

A very considerable advance into this gap was made by Dr. Bazzoni and myself in 1917 using a method which was novel in spectroscopy. Our experiments were directed towards the measurement of the short wave limit of the arc spectra of various gases, and

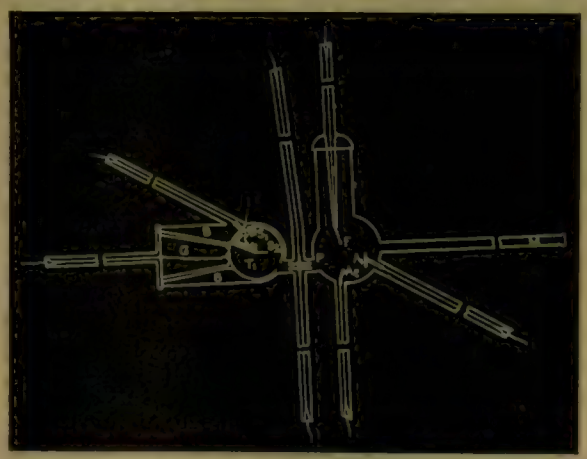

FIG. 2.—Horizontal section of apparatus used for the measurement of the short wave-length limit of arc spectra, drawn to scale.

more particularly of helium, which are generated when such gases are bombarded by considerable electron currents under moderate voltages (Fig. 2). The radiation from the gas generated under impact of the electrons passing from the incandescent tungsten cathode F to the cold anode A_1, falls on the metal strip T, after passing through the gap between the metal plates P, across which an electric field is maintained of sufficient strength to remove any ions present in the radiation stream. This radiation liberates electrons

from the surface of T by photoelectric action, and the energy of the swiftest of these electrons is given by the relation $\frac{1}{2}mv^2 = h(\nu - \nu_0)$, where ν is the frequency of the radiation and ν_0 the threshold frequency of the metal T, h being Planck's constant. The velocity v can be measured by applying a magnetic field perpendicular to the plane of the figure, when the electrons will be constrained to move in spiral paths, the axes of which are parallel to the magnetic field. Only those spiral paths the radii of which lie within certain narrow limits will pass through the gaps S_1, S_2. Consequently, since this radius depends on the velocity of the electrons and on the magnetic field, those electrons which reach the box I in a given magnetic field will have velocities lying between corresponding narrow limits. As the magnetic field is increased it will ultimately curl up the fastest electrons, so that their paths projected on to the plane of the figure lie along the circle $TS_2\ S_1$. Any magnetic field greater than this will give rise to spirals which are too narrow to get into the box I, so that the magnetic field, which is just sufficient to stop the electron current into the box, will determine the velocity of the fastest electrons, and from this datum the equation quoted above enables the greatest frequency present in the radiation to be estimated. In this way we determined the end of the helium spectrum to lie close to the position 15·83 on diagram B of Fig. 1. The corresponding wave-length is about 450 Å.

By 1916 Lyman had succeeded in measuring the wave-lengths of various lines extending to about 600 Å by means of his vacuum grating spectroscope. This instrument of course measures the wave-lengths of the lines with precision, and is the most valuable weapon we have for research in this region. Notable advances have recently been made with it by Millikan, who has made several improvements in technique which have contributed to the success he has attained. These improvements include—(1) the production of special gratings which are ruled with a light touch, so as to have about half the grating surface uncut, and thus throw nearly all the energy into the first-order spectrum; (2) the employment of very high-tension sparks (some hundreds of thousands of volts supplied by Leyden jars and a powerful induction coil) between metal terminals very close together (0·1-2 mms.) in a high vacuum maintained by diffusion pumps. With this apparatus he has succeeded in measuring a large number of lines in the extreme ultra-violet spectra of the light elements lithium, beryllium, boron, carbon, nitrogen, oxygen, fluorine, sodium, magnesium, and aluminium, extending in the case of aluminium to 136·6 Å. This limit is shown at 16·35 on Fig. 1, B.

All these elements exhibit, under these conditions, characteristic line spectra which extend into the ultra-violet, and, roughly speaking, the spectra go further into the ultra-violet with increasing atomic weight of the elements. The spectra differ very much in character as between the different elements; thus boron has but seven strong lines extending between the limits 676·8 Å and 2497·8 Å, whereas carbon has a very complex spectrum extending from 360·5 Å to 1335·0 Å. In fact the spectra of the elements of odd atomic number such as boron tend to be simpler than those of even atomic number such as carbon. The spectra of these elements in this region resemble the X-ray spectra of the heavier elements in this particular, that they consist of groups of lines separated by very wide intervals. Thus with aluminium there is nothing between 144·3 Å (L_α) and 1200 Å, where a new spectrum starts which extends into the visible.

FIG. 3.

There are good grounds for attributing the shorter wave-length groups of the lines of those elements in this region to the L characteristic X-rays of the elements. This will become clear by reference to Fig. 3, which represents the square roots of the various frequencies plotted against the atomic numbers of the corresponding elements. The points encircled between atomic numbers 30-40 (Zn-Zr) belong to the L_{α_1} lines of the elements, the wave-lengths of which have been accurately measured by Friman by the crystal diffraction methods. These points are all practically on a straight line, which, if prolonged in the manner shown by the broken line, reaches the abscissa for atomic number 13 (aluminium) at a value of the ordinate which corresponds almost exactly to the line of wave-length 144·3 Å, which Millikan found to be the longest in his group of aluminium lines in the far ultra-violet. This point is marked thus ⊗ on the diagram. It is of course a long shot from zinc to aluminium, but we shall see later that we have other evidence of the legitimacy of the extrapolation. The other points marked ⊗ refer to the longest lines, and those marked ⊡ to the shortest lines, of the spectra of the various

elements of low atomic weight observed by Millikan. It will be seen that the linear relation between the square root of the frequency of corresponding lines and the atomic number which holds for the higher atomic numbers breaks down in this region. In fact, while there is a general tendency for the corresponding frequencies to increase with increasing atomic numbers, one is no longer an approximately continuous function of the other. The vertical spacing between the points ⊗ and ⊡ for any one element is an indication of the extension of the relevant spectrum. It will be seen that this extension varies in an irregular manner in the sequence of elements from lithium to oxygen. The points shown for lithium are those for the well-known red line 6708 Å and the end, 2299 Å, of the series to which it belongs. No lithium lines were found in the ultra-violet beyond 2299 Å in the region in which the vacuum grating is effective; so that if the allocation of these spectra, for the intervening elements up to aluminium, to the L X-ray series of the respective elements is correct, this series is the L series of lithium. This forms very convincing evidence of the essential similarity of X-ray and visible spectra.

(*To be continued.*)

The Natives of Australia.[1]

By SIDNEY H. RAY.

IN the National Museum of Victoria at Melbourne a special gallery has been devoted to a fairly representative collection of objects connected with the daily life of the Australian aborigines. A very instructive and well illustrated account of the exhibits has been written by Sir Baldwin Spencer, and this gives, in a wonderfully succinct form, what are practically short comparative essays on the arts and crafts of the natives.

There seems to be very little doubt that the first inhabitants of Australia were frizzly-haired people of the old Stone Age, using unground axes, chipped stone knives, and scrapers without handles. They had no knowledge of boats or house-building. Part of this population, cut off by a subsidence which now forms Bass Straits, survived in Tasmania until modern times, but on contact with Europeans became exterminated. In the Museum these people are represented by masks of two males and one female and by a cast from the skeleton of Truganini, the last of the Tasmanians. There is also a collection of their stone implements.

On the mainland the primitive population was supplanted by people in a higher grade of development whose origin is still a matter for discussion. These people are remarkably uniform throughout the continent. The average height is about 5 ft. 6 in.; the skin a dark chocolate colour and never really black; the head long, the hair wavy, not woolly or frizzly like that of the Tasmanian, Papuan, or Negro. The people are nomadic, living in tribes which have distinctive names, and roam within certain clearly defined limits. They have no villages but only camps or clusters of rude shelters. One of the Museum cases contains a representation of a native camp, Fig. 1. This shows the *mia-mia* or shelter made of bark from gum trees resting on the windward side of a rough framework and forming a sort of lean-to. The man and woman are supposed to be returning from a hunting expedition. The woman carries in her hand her digging stick, and on her back a young child secured in its position by the skin cloak. The latter is usually of opossum skins, sewn together with sinews often taken from a kangaroo's tail. The head of the clothed man is decorated with a string forehead band in which are stuck feathers of the black cockatoo. But generally the men wear no clothing. The man in the foreground is making fire with a drill. In connexion with the camp, the *toas* or posts set up by South Australian tribes on departure as a guide to new-comers (see NATURE, February 12, 1920, p. 643) do not appear to be represented in the Victorian collection.

FIG. 1.—Native camp scene.

The languages used differ so much that natives of one tribe cannot understand the speech of their neighbours, and though in some regions, owing to the absence of mountains and rivers, tribes may be closely associated and a few words understood, there is even between these very little community in actual speech. In the Northern Territory the languages appear entirely different in grammatical structure from those in South, West, or East Australia, and approach in character

[1] "Guide to the Australian Ethnological Collection" exhibited in the National Museum of Victoria. By Sir Baldwin Spencer. 142 pp. Third Edition. Illustrated by 33 Plates. Melbourne: Albert J. Mullett, Government Printer, 1922.

the Papuan tongues of New Guinea. Throughout the Australian continent gesture language is very highly developed and forms a ready means of communication when words fail.

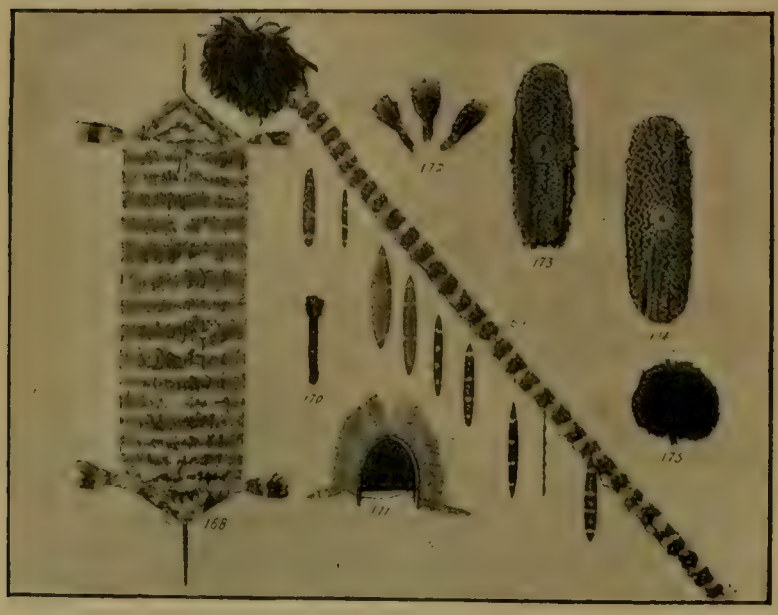

FIG. 2.—Ceremonial objects.

Much has been written about Australian tribes. Most of them have a very definite organisation and are divided into at least two main divisions (sometimes four or eight). Men of one group must marry women of the other, the children belonging sometimes to the father's division, sometimes to the mother's. Relationship names refer to the members of the group. Thus a man uses the term "father" not only for his real father but for all his father's brothers. His "mother" is any of the women whom his father might have lawfully married, and his "brothers" are not only his blood brothers but also his father's brother's sons.

Another social system which is greatly developed among the Australian aborigines is based on the *totems*. As defined by Sir J. G. Frazer, a totem is "a class of material objects which a savage regards with superstitious respect, believing that there exists between him and every member of the class an intimate and altogether special relation." In Australia the totem is an animal or plant, and the native describes himself as a kangaroo, snake, or gum-tree man as the case may be. Some tribes perform ceremonies to increase the totem animal or plant, while in others men may not eat or injure their totem. Sometimes the tribal organisation is based on the totems, sometimes it is sexual, and the women have different totems from the men. Often the totem regulates marriage.

Social organisations and ceremonies are controlled by men whose age, fighting power, or skill in magic make them prominent; but there are no chiefs. The passage from youth to manhood is marked by submission to painful rites of initiation. The knowledge of the sacred or secret ceremonies connected with initiation is forbidden to women and children under severe penalties. Many of the sacred objects connected with these ceremonies, and with the totems, are prominent in the Victorian collection (Fig. 2). They comprise *churinga* (sacred stones and sticks associated with the totems), wands, slabs, and decorations used at initiation.

No Australian weapons are made of metal. Bows and arrows are unknown. Spears are sharpened wooden sticks with barbs attached or cut near the point. Sir Baldwin Spencer describes twelve main types. In some places they are tipped with bone, flaked stone, or spines from the echidna or the sting-ray. The spear is launched by a spear-thrower. This is a stick with a point at one end which fits into a hole in the spear-shaft and gives leverage and accuracy of aim. Spear thrusts are warded off by shields, which are often highly decorated. Clubs of various forms are also used. The most distinctive Australian weapon is the boomerang. This was apparently not used by the Tasmanians. It is a curved throwing weapon varying in size and use, and most of the eastern and southern coastal tribes make a "return" boomerang which when thrown comes back to the thrower.

FIG. 3.—Baskets.

The weapons and implements exhibited have been arranged so as to show their development in various parts of Australia. Thus one of the cases shows transition from an ordinary throwing-stick to a boomerang

and thence to a large double-handed sword-like weapon. Another case shows a transition from a stick to various shapes of knobbed clubs. Two of the latter from Queensland with teeth in the swollen part are suggestive of the "pine-apple" clubs of New Guinea.

The stone implements in the Museum are of special interest. Sir Baldwin Spencer points out that there is no essential difference in type throughout Australia, neither is there any evidence of distinct stages of culture which might be called eolithic, palæolithic, or neolithic. Stone implements which, if discovered in Europe, would be assigned to these stages are found in use in the same camp and district at the present time. The cutting edges of knives and other implements are produced by flaking or chipping, or by grinding and polishing suitably shaped pebbles or cut lumps of stone. Spear-heads and knives are hafted with resin. Spear-heads made of glass, used since the advent of the white man instead of quartzite, are shown in one of the cases. The finely serrated edges are produced by pressure of a kangaroo bone broken and ground into a gouge-like form.

Fire is produced by drill or saw. A piece of hard wood is either rapidly rotated or worked up and down in a groove upon a softer piece, the powder worn away being ignited by the heat of the friction.

Bowls are hollowed from blocks of wood, partly by gouging, partly by burning. Baskets are plaited from grass-stalks, rushes, thin pliant twigs, or split cane. Sometimes they are open, sometimes close enough to contain honey or water. The close baskets are often decorated, as in those from Northern Territory shown in Fig. 3.

String in some places is made of human hair, but in others the possession of the hair of a person gives its possessor power to work harm upon the man from whom it has been cut. String is also made of vegetable fibre, sinew, and fur. Personal ornaments are made of fur, feathers, wood, bone, or shell.

Native art is well represented in the Museum collection. It consists of rude drawings of animals and plants and geometric designs drawn with yellow or red ochre, white pipeclay, and charcoal, or incised drawings with the sharp-edged tooth of an opossum or a flake of flint.

Among the descriptions of the exhibits Sir Baldwin Spencer has given many notes on their use. He has provided a most instructive and useful guide, which cannot fail to interest the student and stimulate the study of Australian ethnography.

Long-Distance Radio Telephony.

THE successful transmission of speech from New York to London, which took place in the early hours of the morning of January 15, shows that the difficulties of long-distance radio telephony are being overcome. The main difficulties are due to absorption of the radio-waves and the muffling of the sounds produced by extraneous noises due to atmospheric disturbances. By carrying out the experiment at night, when the absorptive effects are a minimum, and during the winter months, when the atmospheric disturbances are least, the chances were all in favour of a successful issue. During the first half-hour of the two hours' test, however, the cracklings due to the atmospheric disturbances were plainly audible. Since January 1 measurements have been made daily at the New Southgate Works of the Western Electric Co., Ltd., of the intensity of the signals and of the atmospherics respectively. The results for the first fortnight show that the amplitude of the disturbance due to the atmospherics was less than ten per cent. of the average amplitude of the signals for fourteen hours out of the twenty-four. At this period of the year it is only from 1 P.M. to 11 P.M. Greenwich time that transatlantic telephony is unsatisfactory. When the measurements have been carried out systematically for a year, it will be possible to estimate with fair accuracy the cost of a radio transmission system of satisfactory quality.

It has been found that although the Austin formula gives the daylight strength of radio signals with high accuracy for hundreds of miles over the sea, yet when the distances are measured by thousands of miles it cannot be used. The night values of the signals when the circumstances are favourable can be accurately calculated, as the damping effects are then negligibly small. In the recent test a small frame aerial was used, for the constants of such an aerial can be readily calculated. As there were sixty listeners, each with a head set, considerable amplification had to be employed, and so the test was a specially severe one. Amateurs in this country have occasionally picked up both speech and music sent out by the American broadcasting stations. These, however, are "freak" receptions due to several favourable conditions occurring simultaneously. For commercial radio telephony, communication must be possible at definite times of the day under practically all atmospheric conditions.

In the test the total distance traversed by the speech was first 70 miles by telephone cable from New York to Long Island, where there is a radio station with an antenna 1¼ miles long, supported by towers 450 feet high. About sixty kilowatts had to be supplied to this aerial. A notable economy of power was effected by suppressing the carrier wave between the radio-transmitting and the radio-receiving station, a distance of about 3000 miles. It has to be remembered that the speech could have been sent out with practically equal clearness from any point on the vast long-distance telephone network of the United States.

There can now be no reasonable doubt that transatlantic telephony is possible during a large fraction of the year, and it is quite probable that the result of the tests now being made at New Southgate will demonstrate that radio telephony between Europe and America will be feasible on a commercial basis. This will doubtless have important results on the world's future. It is to be hoped that rapid communication will prevent many of those misunderstandings which too frequently arise between nations.

Obituary.

PROF. J. B. HAYCRAFT.

PROF. JOHN BERRY HAYCRAFT, who died suddenly on December 30, was a figure better known to the older than to the younger generation of British physiologists. A serious illness, which fell upon him (as it fell upon Pasteur) in middle age, affected his scientific work; and the promise and fulfilment of his earlier period have to a certain extent been dimmed.

Haycraft devoted his life to physiology. Throughout it—in spite of ill-health—he held before him the ideal of scientific research. After graduation at Edinburgh he studied abroad in Leipzig. Then, while demonstrator in the physiology laboratory at Edinburgh with Rutherford, professor at the Mason College in Birmingham, interim professor during Rutherford's illness at Edinburgh, and finally professor of physiology at Cardiff, he steadfastly pursued his scientific investigations.

Haycraft's best-known works to-day are perhaps his contributions on animal mechanics and on the senses of taste and of smell in Sir Edward Sharpey Schafer's "Text-book of Physiology"; and his best-known original contribution to physiology is probably his paper on the cross-striation of skeletal muscle (1891). In this latter work he used the ingenious method of taking casts of muscle fibre upon collodion. The impression of the fibre upon the collodion showed the same cross-striated appearance as the original muscle fibre, and Haycraft inferred that the cross-striation is an optical phenomenon due to the varicose shape of the muscle fibrils, which gives different refraction effects in the globular and in the restricted portions of the fibril.

But Haycraft's range of investigation was a wide one: the results of temperature variation (1879); the chemistry of the blood, its coagulation, etc. (1879, 1882, 1884, 1888, 1891); special sense physiology—vision, taste, smell (1883, 1884, 1885, 1887, 1893, 1897, 1910); various contributions to chemical physiology (1889, 1891, 1894); contributions to histology (1879, 1880, 1889, 1890), and to development (1891, 1893, 1895); a theory of amœboid movement (1880); the "muscle sound" (1890); voluntary movements (1890, 1898); the scratch-reflex (1890); elasticity of animal tissues (1904).

Haycraft's chief interest was, however, the physiology of the heart. He published a series of papers in this field: the cause of the first sound (1890); the movements of the heart within the chest (1891); the time of contraction of the papillary muscles (1896); and the changes in shape of the heart during the cardiac cycle (1896)—the two latter papers in collaboration with Paterson. When he resigned his chair in 1920 it was with the intention of continuing his researches on the circulation, and up to the time of his death he applied himself to problems of the pulse-wave in the physiological laboratory at Cambridge.

Haycraft's illness left behind it an impairment of speech which made the expression of his thoughts sometimes a matter of difficulty. This defect in the mechanism of expression was a severe handicap, but did not dim the clearness of his vision and ideals. So far from this being the case, it was in the later part of his life that his vision was crystallised in the development of the Welsh National School of Medicine, and in the Physiology Institute at Cardiff, which will be his chief monument.

In his long tenure of the chair at Cardiff—from 1894 to 1920—Haycraft saw and guided the development of the medical school there until it became the Welsh National School just after his retirement. The modern organisation of that school on the basis of a compulsory degree in science for all its medical graduates, a six years' course of study, and whole-time professors in the clinical subjects, owes to Haycraft more than is commonly realised.

Haycraft insisted that physiology must be the basis of medical education, and fought long for the establishment of a modern laboratory in Cardiff. He was exceptionally fortunate in finding a munificent patron in Sir William James Thomas, Bt., and an enthusiastic architect in the late Col. Bruce Vaughan. The result of this collaboration was the building of the magnificent Physiology Institute in spite of endless discouragement and delay. That Institute, even in its incomplete form one of the largest in the country, carries evidence of his foresight in its detail and arrangement; it is one of the most modern and best planned of physiology laboratories.

His friends will remember Haycraft for his determination in face of opposition, for his vision, and for his high ideal of science; but most perhaps for this, that in spite of all the difficulties which he had to face, he did no mean thing. He was a gentleman, and the magnificent institute which was his vision is his fitting memorial. T. G. B.

SIR JOHN GAVEY.

SIR JOHN GAVEY, who died on January 1, at the age of eighty, was one of the most notable telegraphic and telephonic engineers in this country. He was born at St. Helier in Jersey and began his career in the Post Office in 1870. In 1902 he became Engineer-in-Chief and Electrician to the General Post Office. He was made a Companion of the Bath in 1902, and on his retirement in 1907 a knighthood was conferred upon him.

In his early days at the Post Office, Gavey originated many improvements which greatly increased the speed of automatic telegraphy, and in 1881 he opened the first telephone trunk line connecting two British towns, namely, Newport and Cardiff. In 1894 he succeeded in establishing communication between the opposite sides of Loch Ness, a distance of four miles, by means of the electromagnetic induction between two parallel wires stretched along the banks. This method was subsequently used for establishing communication between lighthouses and the mainland. Gavey was responsible for the organisation of the complete telephone trunk system for Great Britain, and he organised the Post Office telephone exchange system for London. He joined the Institution of Electrical Engineers in 1872, the year after it was founded, and communicated several valuable papers to it. In 1905

he gave in his presidential address to the Institution a masterly summary of telegraphic and telephonic progress and a list of unsolved problems which proved very useful in directing the ingenuity of inventors along promising lines.

Sir John Gavey served on many international committees, including some of the earliest on radio-communication. He was one of the first to appreciate the importance of Oliver Heaviside's theoretical investigations, and to use Duddell's oscillograph in everyday experimental work. He was very highly esteemed by every one who came in contact with him, and the work he did at the Post Office has proved of the greatest value.

Mr. A. H. Curtis.

By the death of Alfred Harper Curtis on January 10, after a few days' illness, the Imperial Mineral Resources Bureau loses a very able and highly-esteemed member of its staff. Mr. Curtis was the second surviving son of the late Alfred Curtis, Town Clerk of Neath, Glamorganshire, and was born on July 12, 1863. Having chosen the profession of engineering, he early gave a practical bent to his studies. As a youth he spent three years with an engineering firm in the Swansea district, and during that time acquired a good knowledge of mining and metallurgical processes. He then proceeded to Owens College, Manchester, where he studied civil engineering and geology, after which he took up the study of mining, mine surveying, and other subjects at the Royal School of Mines, London, and graduated as B.A. at the University of London.

On leaving the Royal School of Mines, Mr. Curtis travelled widely in many parts of the British Dominions and foreign countries, spending long periods in New Zealand and Japan, investigating and developing mineral deposits. His paper on "Gold Quartz Reduction," read at the Institution of Civil Engineers in 1891–1892, gained for him the Telford premium. While in New Zealand, during the period 1896–1902, he was a member of the council and one of the honorary secretaries of the New Zealand Institute of Mining Engineers, to which, in 1898, he contributed a paper on "The Examination and Valuation of Mines."

During the war Mr. Curtis gave much time to the preparation of reports dealing with the mineral resources of the British Empire and foreign countries. In this capacity he worked for a short time at the Imperial Institute, and compiled the publication on "Manganese Ores" issued by the Institute. He later joined the staff of the Imperial Mineral Resources Bureau, and took a prominent part in the compilation of the statistical and descriptive reports issued by the Bureau.

Mr. Curtis was an untiring and conscientious worker, and his death leaves a gap that it will be difficult to fill.

Current Topics and Events.

At the meeting of the Chemical Society held on Thursday, January 18, it was announced that the council had nominated Prof. W. P. Wynne to fill the office of president, which will be vacated by Sir James Walker on March 22.

The gold medal of the Royal Astronomical Society has been awarded by the council to Prof. A. A. Michelson, for his application of the interferometer to astronomical measurements. It will be presented at the annual general meeting to be held on Friday, February 9.

Prof. R. A. Sampson, Astronomer Royal for Scotland, has been appointed General Secretary of the Royal Society of Edinburgh for the remainder of the current session, in succession to the late Dr. C. G. Knott.

Sir Edward Sharpey Schafer has accepted an invitation to deliver in London next autumn the first Victor Horsley memorial lecture. The lecture, which will be given triennially, is the outcome of the work of a committee formed in 1920 to commemorate the services of Sir Victor Horsley to science and the British Empire. The subscriptions received by the committee amounted to more than 1000*l*.

At the meeting of the Institution of Electrical Engineers to be held on Thursday, February 1, the president will present to Mr. J. W. Meares, late local honorary secretary of the Institution in India, and Electrical Adviser to the Indian Government, a salver and cigarette box subscribed for by his friends in India on the occasion of his retirement from the Indian Government Service, and as a token of his valuable services to the profession in India.

The Air Conference, to be held at the Guild Hall on February 6 and 7, will be opened by the Lord Mayor of London. During the Conference the following papers will be presented and discussed: "The Position of Air Transport To-day," by Maj.-General Sir W. S. Brancker; "A Self-supporting Airship Service," by Commdr. C. D. Burney; "The Progress of Research and Experiment," by Air Vice-Marshal Sir W. G. H. Salmond; "Gliders and their Value to Aeronautical Progress," by Col. A. Ogilvie; "Seaplanes," by Mr. C. R. Fairey.

On Tuesday next, January 30, at 3 o'clock, Mr. R. D. Oldham will begin a course of two lectures at the Royal Institution on the character and cause of earthquakes; and on Thursday, February 1, Prof. I. M. Heilbron will deliver the first of two lectures on the photosynthesis of plant products. The Friday evening discourse on February 2 will be delivered by Mr. C. F. Cross on fact and phantasy in industrial science, and on February 9, by Sir John Russell, on Rothamsted and agricultural science.

The Grocers' Company is offering a scholarship (one of three), of the yearly value of 300*l*., with an allowance for necessary expenses, the object being to encourage original research in sanitary science. The appointment will be for one year, but it may be

renewed for a further second or third year. The election will take place in May next. All applications must be sent before April 1 to the Clerk of the Grocers' Company, Grocers' Hall, E.C.2, upon a special form obtainable upon application.

THE Riverbank Laboratories for research in Acoustics, Geneva, Ill., U.S.A., are establishing one or two research fellowships in acoustics, and invite applications for the same from college graduates who have taken advanced courses in physics and mathematics, and shown in their work qualities essential for success in independent investigation. The terms of appointment will be determined by the qualifications of the person or persons appointed. Applications should be sent to Mr. B. Cumming, Secretary, The Riverbank Laboratories, Geneva, Illinois, U.S.A.

THE Minister of Health has appointed the following representatives of the British Waterworks Association and the Institution of Water Engineers as a standing advisory committee to confer with representatives of the Ministry on questions of water supply: Mr. C. S. Musgrave, Mr. A. R. Atkey, Mr. A. B. E. Blackburn, Lieut.-Col. J. R. Davidson, Mr. F. W. Macaulay, and Mr. W. Terrey. The subjects discussed at the committee's first meeting included (1) the steps to be taken for formulating the outlines of a national water policy; (2) the survey of the water resources of England and Wales; and (3) the standardisation and testing of water fittings.

MR. R. I. POCOCK is retiring next March from the post of superintendent of the Zoological Gardens, Regent's Park, to which he has been attached since 1904, and the council has appointed Dr. Geoffrey Marr Vevers to succeed him. Dr. Vevers is at present a Beit Memorial Research fellow and an assistant at the London School of Tropical Medicine. He will have as his staff Mr. D. Seth-Smith as curator of mammals and birds, Mr. E. G. Boulenger as curator of the aquarium and of reptiles, and Miss L. E. Cheesman as curator of insects. Dr. R. W. A. Salmond has been appointed honorary radiologist and Prof. G. H. Wooldridge as honorary consulting veterinary surgeon to the society.

PROF. ALFRED LACROIX, president of the Geological Society of France, has been selected as the recipient of the Hayden memorial geological award for 1923 of the Academy of Natural Sciences of Philadelphia. The award, which is made every three years, and consists of a gold medal, was founded in 1888 in memory of Dr. Ferdinand V. Hayden, at one time director of the United States Geological Survey, "as a reward for the best publication, exploration, discovery or research in the sciences of geology and paleontology." Prof. Lacroix is well known among geologists; he was made professor of mineralogy at the Paris Museum of Natural History in 1893, and in 1901 he was elected a foreign member of the Geological Society, from which he received the Wollaston medal in 1917; in 1904 he was elected a member of the Paris Academy of Sciences, and for the past eight years has been permanent secretary for the physical sciences. His work includes studies of contact and endomorphic metamorphism and a detailed investigation of Mont Pelée. Among previous well-known recipients of the award are Suess, Huxley, Sir Archibald Geikie, Dr. Charles D. Walcott, Prof. H. F. Osborn, and Prof. T. C. Chamberlin.

MR. E. D. SIMON, late Lord Mayor of Manchester, has arranged with the Rothamsted Experimental Station to devote the whole of his farm and dairy herd at Leadon Court, Herefordshire, to a thorough test of the soiling system designed by Mr. J. C. Brown, formerly of the Harper Adams Agricultural College, in which a dairy herd is maintained largely on the produce of the arable land. Mr. Simon has obtained Mr. Brown's services as resident manager, and has authorised the Rothamsted authorities to publish all or any records and accounts that may be deemed helpful to farmers. It is believed that Mr. Brown's system will prove of great value; but in these difficult times the ordinary farmer could not afford to experiment on his own account, and the trial requires more land and dairy cows than could be provided at a college or an experimental farm. The experiment will serve a valuable purpose in showing how far the various modifications introduced will be financially advantageous to the dairy farmer, and agriculturists generally will greatly appreciate Mr. Simon's generous action.

ATTENTION was recently directed in these columns (November 11, p. 642) to the probable use of the cinema in England and France as a means of agricultural education among farmers. It is interesting to note that the United States Department of Agriculture has employed this method for the last nine years. At the present time they have 150 films available dealing with many branches of farming activity, and with rural life generally. Special attention is paid to the control of disease, both of animals and plants, and the best methods of crop production. The American parks and game preserves, which are in the charge of the Department of Agriculture, also receive attention, and their value to the nation is illustrated from many points of view. It is probable, however, that the films dealing with Extension Service activities of the Department are the most important. Of recent years the development of co-operation, both for the business interests and the amenities of rural life, has proceeded at an ever-increasing rate. There is no doubt that the progress of this movement has been, and will be, greatly stimulated by the use of films; they cannot, of course, replace in any way the valuable personal contact with the farmer, which is the corollary of an adequate research and advisory service, but they can help greatly in disseminating a general idea of the expert assistance that is available.

ON two previous occasions last month (December 2, p. 743, and December 30, p. 884) we referred to film displays in connexion with the Mount Everest Expedition of 1922. Another effort to place before the public a record of the results obtained, is the exhibition of

pictures at the Alpine Club Hall, Mill Street, Conduit Street, W.1. These pictures, which will be on view until February 6, include some 152 photographs and 52 paintings in oil and water colour. The photographs are chiefly by Capt. Noel, showing the personnel of the expedition, the camps and ground traversed, and the Tibetan people. Among the last-named group are several of the Rongbuk monastery and its inmates, including two telephotographs of the Chief Lama, who, as the supposed incarnation of the god Chongraysay, could not be approached sufficiently for an ordinary photograph. There are several fine photographs of the East Rongbuk glacier by Capt. Finch, some of them showing the tremendous ice-pyramids which had to be traversed, varying in height from 30 to some 300 feet. At nearly 23,000 feet the Chang La camp was pitched in very curious surroundings; the peculiar snow formation shown behind the camp in the picture was only met with at this place. The photographs follow the climbing to a height of some 26,000 feet, and one shows the party a few minutes before the disastrous avalanche. The view of Changtse and Gyachung Kang from Mount Everest, taken at an altitude of 26,985 feet by Mr. Somervell, creates a record in photography. Among the more striking scenic effects are the wind-blown snows on the east slopes of Everest, and the sunset on the north face. Copies of the latter photograph and several others of the collection may be purchased. The impressive scenes in water colour and oil by Mr. T. Howard Somervell are also for sale. The proceeds will be spent on a third expedition.

THE weather over England in 1922 had no outstanding feature like the drought in 1921, and it will go down to posterity as a fairly normal year meteorologically. Heavy gales were somewhat more frequent than in late years, especially over the southern portion of the Kingdom. Observations at the Royal Observatory, Greenwich, show that the mean temperature for the year was 49·4° F., which is 0·7° less than the normal, using the period of 35 years, in agreement with the system adopted by the Meteorological Office. The warmest month was June with a mean temperature of 60·3°; this was the only month with the mean temperature above 60° and the only month with the mean of the maximum readings above 70°. January, February, May, June, and December were the only months with an excess of temperature. The coldest month was January, with the mean temperature 40·3°, which is 1·7° above the normal. There were two days in May with the shade temperature above 90°, and there was one day in January, April, October, and December with the shade temperature less than 25°. Rainfall for the year, using the results for the civil day, measured 23·24 inches, which is 0·26 in. less than the normal. July was the wettest month with 3·20 in., which is 0·96 in. above the normal; the next wettest month was December with 2·92 in., which is 0·66 in. more than the normal. October was the driest month, with the total rainfall 0·93 in., which is 1·60 in. less than the normal. Rain fell in all on 178 days, which is 15 days more than the normal, and in both January and July rain fell on more than 20 days. November had only 8 days with rain. Sunshine was registered at Greenwich for 1469 hours, which is 9 less than the normal: the sunniest month was May with 284 hours, the least sunny, November with 26 hours.

THE January number of the *Museums Journal* prints the report of a committee appointed by the National Society of Art Masters, the Incorporated Association of Headmasters of Secondary Schools, the Association of Headmistresses of Girls' Secondary Schools, and the Museums Association, to inquire how far the system of circulating objects from the Victoria and Albert Museum meets the needs of the provinces. Besides recommending that the circulation collections should be systematically completed and brought up-to-date, the committee suggests that the local museum might become a local sub-circulation department of the Victoria and Albert Museum. It ends by pointing out that, "whilst the total vote for Education has grown enormously, the sum allocated for the museum side of Art Education in the Provinces has been practically stationary for generations, and bears no proper relation to the sum available for education as a whole." And yet on its museum side Art Education is treated generously as compared with other branches of education.

AUTHORS and readers will be interested in the authoritative statistics of the cost of book production published in the excellent new Catalogue of the publications issued by Mr. Milford for the Oxford University Press. In the year ending March 31, 1914 the Press issued 157 new books at the average price of 7*s.* 11*d.*, or 0·37*d.* per page. The corresponding figures for the year ending March 31, 1922 were 115 books at the average price of 11*s.* 10*d.*, or 0·64*d.* per page. These figures concern only those books, in their nature unremunerative, which the Press produces as a service to education and learning. "It will be readily understood that the cost of the present output is higher than that of the pre-war output (though the rise in the price to the public does not show an equivalent increase); and the moral is easily drawn, that the output can be restored to the old level only by the activity of the Press in the production of remunerative books and by increased support from the public." It may be also noted that the concluding volume of the Oxford Dictionary will, when completed, have cost not less than 50,000*l.*

IN the article on the last report of the Development Commissioners, which appeared in NATURE of December 30 (vol. 110, p. 865), the statement was made "that the report does not contain, as in the past, an account of the present finances of the Fund." The Secretary to the Commissioners writes to point out that this statement, which we regret, is incorrect; for such an account does, in fact, appear in the body of the report, and it shows that the balance at the credit of the Fund on March 31 last was 1,337,336*l.*, including 850,000*l.* received under the provisions of the Corn Production Acts (Repeal) Act 1921. The advances made during the year 1921–22 were, in the aggregate, 385,185*l.* The *net* balance available for annual

advances to meet the cost of existing schemes is stated to be 128,000*l.* only, against an estimated requirement of 200,000*l.* There may be some ground, therefore, for the apprehension expressed in the article as to the future adequacy of the Fund.

REFERRING to a remark made in the notice of his book "The Supremacy of Spirit" in NATURE of January 13, p. 45, Mr. C. A. Richardson writes to say that his purpose was not to attempt to deal at all adequately with scientific objections, but to show that (1) the evidence for the alleged facts is now of such a kind as to merit serious consideration and investigation by a scientific committee; (2) the alleged facts are in terms of his philosophical theory.

THE January list of new books and new editions added to Lewis's Medical and Scientific Circulating Library during October–December has just reached us. Although intended primarily for subscribers to the library, it should be of service to many others, being a general guide to medical and scientific works published in the past three months. The list, which is classified according to subjects, is to be obtained free of charge from Messrs. H. K. Lewis and Co., Ltd., 136 Gower Street, W.C.1.

THE spring announcement list of the Cambridge University Press contains particulars of many forthcoming books of science. Among them we notice "The Air and its Ways," by Sir Napier Shaw, being the Rede Lecture for 1921, and other papers dealing with the physical explanation of the atmospheric circulation and with the application of meteorology to agriculture; "Relativity," forming the second of the supplementary chapters to Dr. Norman R. Campbell's "Modern Electrical Theory"; a newly arranged and enlarged edition of "The Mathematical Theory of Relativity," by Prof. A. S. Eddington; the "Collected Scientific Papers" of the late Dr. J. Aitken, containing some thirty-seven papers on atmospheric dust, fogs and clouds, air temperatures, and other scientific subjects, added to which is a sketch of the life and work of the author; and "Glass-Making in England," by the late H. J. Powell of the Whitefriars Glass Works, in which an account of glass-making in all its branches is given from the Roman period to the Great War.

Our Astronomical Column.

OCCULTATIONS OF STARS BY THE MOON.—On the night of January 27, the moon will pass over a number of the stars forming the well-known group in Taurus called the Hyades. The bright star Aldebaran is among those which will be hidden. The times of occurrence for four of the brighter stars will be as under:—

	Mag.	Disappears. h.	m.	Reappears. h.	m.
γ Tauri	3·9	2	57	3	57
0′ Tauri	4·2	8	31	8	56
+15° 637	4·8	9	26	10	39
Aldebaran	1·1	12	35	13	30

The moon will be about 10½ days old at the time and the stars will disappear at the unillumined side, and reappear at the bright edge of the disc.

The event may be witnessed with a small telescope, and it is possible that Aldebaran may be seen by acute, unaided vision nearly up to the time of its disappearance, which will occur 35 minutes after midnight. The moon will be due south at 8h and will be 55 degrees above the horizon at the time. There will be four other occultations of Aldebaran during the next 12 months, on March 23, October 27, November 24, and January 17, 1924.

OBSERVATIONS AT WALLAL OF THE ECLIPSE OF SEPTEMBER 1922.—The winter number of the *Chaldaean* (vol. v., No. 17) contains an interesting account of the observation of the eclipse at Wallal on the west Australian coast by Messrs. J. Hargreaves and G. S. Clark-Maxwell. Their principal instrument was the 19-ft. camera with lens of 4-in. aperture lent by Father Cortie, and the 8-in. coelostat lent by the Royal Irish Academy; these were the same instruments as were used at Sobral, Brazil, in 1919, when they gave a result in close accord with Einstein's predictions. But in 1922 the stars were too faint to be photographed with a ratio of aperture to focal length 1/57, and the instrument was simply used as a coronagraph. A large number of successful exposures were secured with a range of 1 to 80 seconds, so that they should give good details both in the inner and outer regions. Successful plates were also secured with the smaller cameras; a declinometer, to record magnetic variations during totality, failed owing to a smoky lamp. The darkness during totality is stated to have been considerable, necessitating the use of lamps for plate-changing, etc. The extension of the corona on some of the plates is 4 solar diameters, which is quite satisfactory.

A gale rendered re-embarkation very difficult, one boat sinking in the surf. None of the important pieces of apparatus were in it, and the articles were recovered. This experience shows that it would have been quite impossible to land the very heavy packages of the Christmas Island party at Wallal; it is a slight mitigation of the disappointment that they suffered to realise that they chose the only station that was reasonably possible in the circumstances.

SPECTROSCOPIC PARALLAXES OF A-TYPE STARS.—The earlier spectroscopic parallaxes were restricted to types F, G, K, M; but, as was recently noticed in this column, Messrs. Adams and Joy have found that the state of sharpness or nebulosity of certain metallic lines in the spectra of stars of type A forms a trustworthy guide to absolute magnitude. The calibration of the correlation curves is effected both by trigonometrical parallaxes and by the group parallaxes of stars in moving clusters. The average differences of the spectroscopic and trigonometric parallaxes (without regard to sign) are +0·0131″ (104 stars), spectroscopic and group parallaxes +0·0077″ (82 stars). The systematic differences are 0·0000″ and −0·0014″ respectively. A list is given (*Astrophys. Journ.*, November 1922) of 544 spectroscopic parallaxes of stars in Boss P.G.C., including a number of members of the Taurus, Perseus, and Praesepe streams. The parallax of Praesepe is given as 0·013″.

A test of the values found is afforded by plotting parallax against proper motion. The resulting graph is nearly straight, showing an increase of proper motion from 0·000″ to 0·400″ as the parallax rises from 0·009″ to 0·058″. It is found advisable to omit Sirius, the large parallax of which unduly affects the mean of its group.

Data are still wanting for finding the parallaxes of stars showing the *c* characteristic, α Cygni being the leading example. Its absolute magnitude is estimated as −4 or −5.

Research Items.

WEAVING IN ANCIENT EGYPT.—Mr. Winlock's discovery of a model weaving shop in the XIth dynasty tomb of Meheńkwetre at Thebes has caused a fresh revival of interest in the subject of ancient Egyptian looms. Two articles in *Ancient Egypt* (Part iii., 1922) are devoted to branches of this subject. Mr. Winlock deals with heddle-jacks and Mr. A. C. Mace with loom weights in Egypt. Some interesting pictures from other tombs dealing with processes of weaving render it easy to follow the lucid descriptions in the text.

BRASS-CASTING IN THE CENTRAL CAMEROON.—The methods of the artists who produced the remarkable series of brass-casting at Benin are illustrated in a paper by Mr. L. W. G. Malcolm, published in the January issue of *Man*. Mr. Malcolm found the art continued to the area in south-west Adamawa, the principal towns being Banyun and Bagam. As a rule the material now used is of European origin. In the north it appears that tin was formerly brought from northern Nigeria, and it has been suggested that copper may have come from the Katanga area of the Congo. In all cases the casting is done by the *cire perdue* process. The articles produced by the Eghāp tribe are generally pipe-bowls, personal ornaments, grotesque animal and bird forms, perfume flasks and bells. Several interesting examples of tobacco pipes used by the Eghāp head-men are illustrated by Mr. Malcolm.

TRIASSIC REPTILES AND STEGOCEPHALIANS FROM TEXAS.—Publication No. 321 of the Carnegie Institution of Washington is devoted to "New Reptiles and Stegocephalians from the Upper-Triassic of Western Texas," by E. C. Case. After sketching the geology of the borders of the Staked Plains in Texas and New Mexico, where these fossils occur, the author proceeds to the description of *Buettneria perfecta*, a new genus and species of Stegocephalia, that has its nearest relations in Metoposaurus. There follows a full description of *Desmatosuchus spurensis* and the sub-order Desmatosuchia, which were originally described by Case in 1920, accompanied by a restoration of *D. spurensis*. Of new parasuchians there are *Promystriosuchus ehlersi*, a fully mature phytosaur of the Mystriosuchid group, of small size and distinct in its characters from any previously described, and *Leptosuchus crosbiensis* and *L. imperfecta*. Descriptions of isolated bones of parasuchians and the remains of a small dinosaur, with notice of some coprolites and a small fragment of a jaw containing a singularly shaped tooth reminiscent of the teeth of Diadectes, terminate this important monograph, which is well got up, as all the publications of the Institution are, and most excellently and abundantly illustrated.

PHENOLOGICAL OBSERVATIONS ON PLANTS.—Dr. E. Vanderlinden has published (Recueil de l'Institut botanique Léo Errera, t. x.) further results of his observations on the relation between the time of flowering and various climatic conditions. He has now observed a series of woody plants during the years 1896–1920, and of herbaceous plants from 1910 to 1920. The results are tabulated and also plotted in relation to external factors, such as maximum and minimum temperature, soil temperature, and hours of sunlight. Dr. Vanderlinden finds that advancement or retardation of the flowering period in favourable or unfavourable seasons is much less in the case of herbaceous than in those of woody plants. This difference he attributes to the fact that in the latter the reserve materials accumulated to supply the new flowers occur in the aerial parts of the plant and are more exposed to the influence of atmospheric variations. Both woody and herbaceous plants show a periodicity in the distance between the two extreme dates of flowering. These are considerable in April but decrease onwards, reaching a minimum towards the end of June, and then show a progressive increase. That is to say, the flowering periods of the last half of May and the whole of June are less affected by climatic variations. The chief factor in inducing this periodicity is the less prevalence of inhibiting temperatures during the summer months as compared with the spring. The observations were made at Uccle in Belgium.

THE CONDITION OF THE EARTH'S INTERIOR.—The criticism by Mr. W. F. Jones of Prof. T. C. Chamberlin's views as to the planetesimal origin of the earth has been mentioned in a letter published in NATURE (August 19, 1922, p. 249), and it is only fair to state that Prof. Chamberlin has published a reasoned reply to Mr. Jones in the *American Journal of Science*, vol. 204, p. 253, October 1922). He maintains that the evidence as to the propagation of earthquake-waves, which originate "within the shell not very far below the surface," is entirely opposed to any theory of the existence of a molten interior in the earth at the present day, while the conception that such an interior might have arisen by condensation of solid particles in the past is incompatible with the planetesimal hypothesis. He has probably not yet had time to consider J. Joly's startling suggestion that changes within the earth may give rise to bursts of radioactivity, and that these may bring about the complete melting of a previously solid earth. Chamberlin remarks that the proofs given by Coleman and others of the batholitic nature of the granite that invades the outer and ancient sedimentary crust are destructive of the idea of an underlying crust of light material, such as might have gathered round a molten globe. To many this argument will not appear entirely sound. The occurrence of batholites forming intrusive gneisses over very wide and separated areas seems to imply the existence of a crustal layer of granitic composition from which they have ascended as remelted representatives.

WEATHER IN THE PHILIPPINES.—Hourly meteorological observations made at the Central Observatory of Manila during the calendar year 1919, prepared under the supervision of Rev. José Algué, S.J., Director of the Weather Bureau, have recently been received. Hourly readings are given of barometer, temperature, humidity, and wind velocity. During the year nine typhoons visited the Philippine Islands, and in all there were twenty-five depressions or typhoons throughout the Far East. These were all observed from June to December, no typhoons occurring from January to May. The Manila rainfall broke all records since the formation of the Observatory in 1865, both as to the monthly and annual amount. In August the total fall was 78·09 in.; the previous maximum fall in any month was 57·88 in. in September 1867. In the whole year the total rainfall at Manila was 154·39 in., almost double the normal annual fall; the greatest previous record in any year was 117·27 in. in 1867. The lower parts of the city of Manila and of several provinces of the western part of central Luzon were flooded from the

end of July until about the middle of September. During the first part of the year the weather had been rather dry throughout the Archipelago. Extraordinary seismic activity occurred during the year. There were 151 earthquakes felt within the limits of the Archipelago; only two shocks, on April 28 and August 14, were of destructive character. In the Central Observatory, Manila, the seismographs recorded 420 disturbances due to insular and distant earthquakes. At Butuan the seismic disturbances numbered 1076.

ULTRA-VIOLET PHOTOGRAPHY OF OLD MANUSCRIPTS.—In a paper by Prof. The Svedberg and Hugo Andersson, which has just been published in the *Photographic Journal* (No. 63, 1923, pp. 30-32), a very instructive example is given of the use of ultra-violet light in photographing old manuscripts. When a palimpsest is illuminated with intense ultra-violet light it is found that those parts of the parchment where the old, and subsequently erased, writing was, have lost the power of strong fluorescence which is

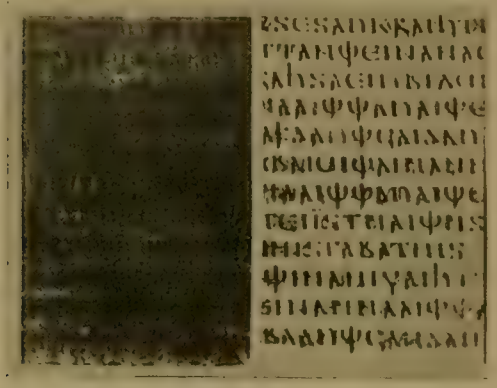

FIG. 1.

still exhibited by the untouched parts of the parchment. Kögel, in 1915, worked out this method for deciphering such parchments, and Svedberg and Nordlund used it later for deciphering the famous "Codex Argenteus" in the University Library of Upsala, and for other similar purposes. The difficulties attaching to this method lie in the very long exposures necessary to obtain a negative by means of the comparatively feeble fluorescence, several hours' exposure being necessary through the filters used to cut off the visible light from a quartz mercury lamp. The Wratten department of the Kodak Company has recently put a new U.V. filter on the market, and by means of this filter, Prof. Svedberg and Mr. Andersson have succeeded in cutting down the exposure to 15 minutes, with the results illustrated in Fig. 1, which shows the comparison between an ordinary photograph and the fluorescence photograph. The Wratten filter is superior to the Zeiss U.V. filter hitherto used for such purposes, in that it is much more transparent (about 10 times) in the long-wave part of the ultra-violet (391-344 $\mu\mu$).

THE FADING OF COLOURS.—An interesting problem, the fading of colours of objects in museums when exposed to light, was dealt with in a paper read by Sir Sidney Harmer, Director of the Natural History Departments of the British Museum, before the Royal Society of Arts on December 13. It is common knowledge that many colours fade when exposed to strong sunlight, but the relative injuriousness of diffused daylight and artificial illuminants is less known. Experiments by Dr. Russell and Sir William Abney led to the following main conclusions: (1) fading is due to the action of light and not to moderate heat; (2) it does not take place *in vacuo*, *i.e.* in the absence of oxygen and moisture; and (3) the rays of the violet end of the spectrum produce the greatest amount of fading. Experiments with various glasses devised to check the transmission of ultra-violet rays have been made. Some of these have a useful effect, but it appears that in general the use of tinted glasses merely delays fading and does not prevent it, in the case of fugitive colours. The best glass for the purpose had a distinct yellow coloration, rendering its use for cases scarcely practicable. As examples of the length of continuous exposure necessary to cause fading it is mentioned that the wings of certain moths showed appreciable fading in 10-21 days; on the other hand, the fur of the tiger required 175 days, and of a brown horse and antelope 1485 days, before there was perceptible change of colour. According to these experiments direct sunlight was about from 20 to 70 times as injurious as electric light, and diffused daylight about six times as injurious. While too much importance should not be attached to such figures, there seems little doubt that illumination by electric light is less liable to cause fading than natural light, and the question arises whether very valuable specimens, or those with highly fugitive colours, might not be lighted entirely by artificial means. Most artificial illuminants contain less ultra-violet energy than daylight. But apart from this it is possible that a much lower intensity of illumination might suffice to enable specimens to be seen.

STANDARDISATION OF EXPERIMENTAL TANK DATA.—In view of the fact that nearly all the important maritime nations of the world have experimental tanks, the introduction of international systems for the presentation of results would be extremely helpful to experimenters and designers. Mr. Telfer, in a paper, "The Presentation of Ship Model Experiment Data," read before the North-East Coast Institution of Engineers and Shipbuilders, on December 8, discusses the existing systems of presentation and their relative usefulness. He points out that the basis of any system should be dimensionless, and that the units forming this basis should be international, besides giving results finally that can be readily interpreted by practical men without any arithmetical unravelling. Experimental work up to the present has been presented in widely different forms. Froude used expressions Speed/(Vol.)$^{\frac{1}{6}}$ and Power/(Vol.)$^{\frac{1}{2}}$(Speed)^{3}, giving results for a one cubic foot model. Taylor, on the other hand, expresses his results per ton of displacement. Mr. Telfer suggests that results could be made international by adoption of the metric system and presenting results for models of one metric ton displacement, adopting Power/(Volume)$^{\frac{1}{2}}$ and Speed/(Volume)$^{\frac{1}{6}}$ as the basis of the presentation. He also suggests the adoption of definite symbols, these being selected "from international philological considerations, all related symbols being mnemonically appropriate and above all typographically simple rather than typographically unique." Such an international code is greatly needed. There is at present an awkward disregard for standardisation of symbols even among experimenters of the same nation. It is to be hoped that this present paper will help forward in ship model data what has already been adopted in aeronautical work. Before setting up an international system such as is suggested, it would be best for a representative committee to inquire into the basis to be adopted, and also to undertake the transference into this system of all existing data.

The Distribution of Life in the Southern Hemisphere, and its Bearing on Wegener's Hypothesis.

ONE of the most important results of the acceptance of Wegener's theory of the palæogeography of the world would be the simplification of the facts of the Permo-Carboniferous glaciation of Australia, India, South Africa, and South America by bringing the glaciated areas together into one single glaciated region. It is undoubted that if this were done much of the difficulty of accounting for the simultaneous glaciation of regions so diverse in latitude would disappear. Considerable interest, therefore, attaches to the recent discussion on Wegener's hypothesis, which was held before the Royal Society of South Africa, for its bearing on this important aspect of the subject.

The general attitude of the geologists who took part in the discussion was one of suspended judgment. It is admitted that the folded ranges of the Sierras of Buenos Aires appear to be of similar age and structure to those of the southern folded belt of the Cape Province, and would be brought into fairly accurate alignment if the South American coast were fitted into the African coast after the manner of Wegener's map of Carboniferous land distribution, but it was held that this might be accounted for in several other ways more in accord with the known facts of geology. On the other hand, the very close and detailed homology of the Tertiary deposits of Grahamland and Patagonia as described by Gunnar Andersson forms one of the most relevant pieces of combined geological and palæontological evidence from the southern hemisphere in support of the theory.

Discussing the zoological evidence, Mr. K. H. Barnard concludes that the zoologist, far from being able to help in formulating an explanation of the palæogeographical history of the continents, was, in reality, entirely dependent on the geophysicist and geologist, and that in some cases the facts of present-day distribution were capable of interpretation in terms either of a far-reaching equatorial Gondwanaland or a compact polar Gondwanaland. There is little to choose, for example, between Watson's theory of the dispersal of acarid snails from S.E. Asia [equatorial Gondwanaland] and Hedley's theory of their origin in Antarctica [polar Gondwanaland], and whichever geological theory best explains the palæogeographical changes must be used as a basis by zoologists. Similarly, if the ancestors of the fresh-water crayfishes originated in an arm of the Indo-Pacific which gradually penetrated into polar Gondwanaland in pre-Jurassic times, the same results will follow as those sketched out by Ortmann for post-Jurassic times. The distribution of Peripatus, on the other hand, is apparently best explained on the polar Gondwanaland hypothesis. If the distribution of the species of Peripatus is plotted on a polar projection map, it is remarkable that the Peripatopsidæ, the more specialised group, occupy a central position, while the Peripatidæ, the more primitive, are peripheral. The most important zoological evidence in support of Wegener's theory is provided by the isopod, Phreatoicus. At the present time it is found in Australia, Tasmania, New Zealand, and South Africa. There is the closest possible likeness between some of the Australian species and the Cape form. In Australia there is also a fossil species of Triassic age, which provides almost positive proof that the animal was not only palæogenic, but also austrogenic, and that the regions where it exists to-day were once in the very closest relationship to one another.

Dr. Peringuey, discussing the entomological evidence, concludes that the present distribution of insects is as readily accounted for by the geological theories now obtaining as by Wegener's hypothesis, and believes that the latter will receive little if any support from entomology. He agrees that the key will be found in palæo-entomology, but is forced to admit that the evidence from fossil insects is at present too inadequate to be of value. Discussing the special case of the Coleopteron genus Carabus, first found in Jurassic times, Dr. Peringuey points out that it is unknown in the Old World south of the Sahara, but one species occurs in St. Helena and seven in Chile. He regards the St. Helena and Chilian forms as survivals from an equatorial Gondwanaland, in isolated spots at high altitudes, and not as evidence of the former connexion of South America and St. Helena, in their present form, with South Africa, where the genus is absent, or with Australia, where the genus is unknown but where its vitality should have ensured its success. On the other hand, the nearest ally of Carabus, the genus Calosoma, has three species in South Africa, three in Australia, one in the Galapagos Islands, and one in Patagonia, a distribution which seems to support the unity of the continents alleged by Wegener. In Australia there is a group of large Curculionidæ, one of the families of Coleoptera, which so much resembles a purely South African group of the same family that, at first sight, the two might be taken to represent the same stock in two now widely separated continents. Dr. Peringuey, however, regards this as a case of convergence.

Prof. Compton regards the botanical evidence as completely opposed to Wegener's theory. The perfection of the means of dispersal of plants renders many of the facts as to the modern distribution of ancient groups (Cryptogams) almost valueless as an indication of former land connexions. Recent phyla only, especially the Angiosperms, can be relied on. The Angiosperms arose during Cretaceous times, and most modern families are represented in the Eocene. The Wegener hypothesis contemplates a wide disruption of South Africa and Australia in the Jurassic epoch, but South Africa and South America were only separated by a very narrow strait at the end of the Cretaceous period. Yet the floristic resemblances between temperate South Africa and South America are much less conspicuous than between temperate South Africa and Australia. The floristic relationships between South Africa, South America, and Australia are best explained as being due to lateral migration, perhaps in the warmer Miocene, from a comprehensive tropical belt of vegetation, containing most of the great Angiosperm families, which stretched round the world except the Pacific. The south temperate floras, therefore, are linked through the tropics except for South America and New Zealand, which certainly seem to have been connected by land, via Antarctica, in the Miocene. The modern distribution of the Rutaceæ is an excellent instance of the progress of migration southwards as well as northwards from this tropical belt, and tentative explanations of the distribution of the Proteaceæ and Restionaceæ may be given on the same lines. Dr. Du Toit regards the palæobotanical evidence as too fragmentary for botanists to do more than make guesses at the probable origin of the South African flora.

The net result of this interesting discussion is to emphasise the importance of further work on the palæontology of the southern hemisphere. In that direction alone will be found the key to the correct interpretation of the known facts of the present day distribution of animals and plants, and of the palæogeographical changes which have taken place.

The Position of the Scientific Worker.

AT the annual council meeting of the National Union of Scientific Workers, held at the Caxton Hall, Westminster, on January 13, and at the annual dinner which followed, the main theme of the resolutions which were adopted, of the various speeches made, and of the reports presented, was the methods by which the position of the scientific worker could best be improved. The late Government, it was alleged, had adopted a short-sighted policy with regard to most of those State activities which promised to have the most uplifting and far-reaching effect upon the efficiency and well-being of the nation. It had practised so-called economy by reducing expenditure on education and scientific research, at a time when our chief commercial rivals were increasing their expenditure in that direction.

To the want of appreciation and understanding of the importance of science by the members of the late Government, culminating in drastic reductions in the various research departments, were attributed most of the present troubles of scientific workers. Within the past twelve months "economies" have been effected in those departments of the State and municipal services which do not show an immediate return for the money expended. The inevitable effect will be stagnation in peace, and in war hurried, and therefore uneconomical, research. It is true that the Geddes Committee last year expressed the view that there is little possibility of a further war of any magnitude for the next ten years; but just as their prognostications in that respect appear doubtful at the moment, judged by the trend of current events, so is their corollary to the effect that research in this country can either be slowed down, or, in some instances, abandoned altogether. This is a doctrine of despair, and was characterised as such by members of the council of the Union, and by their guests, Sir Thomas Holland, Mr. William Graham, and Mr. H. N. Brailsford.

Mr. Graham said that there were three aspects of the work of the National Union of Scientific Workers which particularly interested him. The Union must be interested in conditions of employment and remuneration, and he felt that it was a serious mistake, if not a positive crime on the part of the community, to starve the body of investigators upon whose efforts so much depends. The Union would also be alive to the importance of according greater recognition to the work of the universities, and to the contribution that science can make to the restoration of economic prosperity in the world. He thought there was a distinct danger to the universities in the present economy campaign. Before the war the country was making only a limited provision for the universities and other educational institutions. As a member of the Oxford and Cambridge Universities Commission, he had had an opportunity of making a careful examination of university departments and university finance, and he hoped that the Bill to be presented to Parliament next session would result in the present grant being more than trebled. It would not do to rely in the future, as in the past, on philanthropy. Much larger sums of public money would be required, and scientific workers could argue strongly that they did not claim it selfishly, but for the benefit conferred on the nation by their investigations. The methods of science are needed in these days of reconstruction, and if adopted would undoubtedly increase production and help in resisting the lowering of the standard of life, which is a pressing danger in every country. Sir Thomas Holland fully endorsed these views, adding that the Government should understand that at least 80 per cent. of the expenditure of a teaching and research institution must be disbursed as salaries to the staffs. A strong and united body of scientific workers is a necessity if salaries are to be improved and the right atmosphere created. Unfortunately the dignity of the work in most people's eyes is apt to be commensurate with the sums paid for it, so there is every reason why the Union should put the question of remuneration in the forefront.

Dr. Alan A. Griffith, the retiring president, in his address, dealt with this matter from a rather different point of view. He suggested that scientific workers should free themselves from the necessity of having to beg from their beneficiaries the wherewithal to improve the efficiency of their labours, by setting up a business organisation for the exploitation of their discoveries and inventions. In providing specifically for the evolution of great inventions based on pure research, it would fill the gap between science and industry, which has, in the past, so seriously hampered the material utilisation of scientific discoveries.

The Hydrogen-ion Concentration of Sea Water.

A RECENT number of the Journal of the Marine Biological Association (vol. xii., No. 4, October 1922) contains a series of papers by Dr. W. R. G. Atkins which make a contribution of conspicuous value towards our knowledge of the fundamental conditions that control vital production in the sea. After a short review of the literature the author considers what lines of research his study indicates, and then follow six memoirs which deal, in the most interesting way possible, with some of the problems that have suggested themselves.

First in importance is a series of determinations of the H-ion concentration in the open sea between Plymouth and Ushant, and round Land's End into the mouth of the Bristol Channel. In the open sea the "pH" values varied between 8·27 and 8·14; round Land's End the variation was between 8·18 and 8·14, and in Plymouth Sound it was about 8·10. Now "pH" means the logarithm of the reciprocal of H-ion concentration expressed in grams per litre of water. High values (up to about 10) mean high values of the "alkalinity" as represented, for example, by the quantity of N/100 acid necessary to decolorise sea water made pink by the addition of phenolphthalein. Low values (down to about 6) mean "acidity" of the sea water by reason of the presence of unusually large quantities of carbonic acid.

Biological relationships are associated with these variations in the pH-values. Thus, there is a decrease of about 0·05 between high and low water, and this is due to the influence of the water draining away from the shore zones; over a bed of Laminaria the water was more alkaline than in the immediate neighbourhood, and in rock pools pH sank by as much as 0·25: this is the result of photosynthesis by algæ which remove carbonic acid. In the aquarium tanks the pH-values sink to 7·6. When it is less than this, carbon dioxide is in excess, and at 7·3 there is evident distress in the respiration of fishes. At 7·1 the water becomes

foul and smells badly, and at 6·4 we have the conditions produced by seaweeds rotting in a jar of water. From the change in *p*H-values the quantity of carbon removed from solution in the sea in the form of carbon dioxide, and built up, by photosynthesis, into the tissues of marine plants, can be calculated. Represented as a hexose, the author gets the surprisingly great production of 250,000 kilograms produced per square kilometre of sea, in the English Channel between July and December. From similar observations made at Port Erin, Moore found a production of 300,000 kilograms per square kilometre during the six months that included the vernal maximum of diatom reproduction.

The other researches are equally important, especially as they deal with methods. The practice of determining organic matter by oxygen consumed in water samples is criticised. The reaction of the sap in the cells of marine algæ has been studied: it is shown to be almost neutral, in contrast with the acid sap of most land plants. Methods of finding the H-ion concentration in living algal cells are developed, and the influence of changes in *p*H is shown to be a factor in the distribution of shore weeds. Finally—a most useful result—the preparation of permanently acid-free formalin solutions is described. This series of papers by Dr. Atkins has particular interest for marine biologists. J. J.

The Structure of Coke.

SIR GEORGE BEILBY has contributed an interesting paper entitled "The Structure of Coke, its Origin and Development," to the Transactions of the Society of Chemical Industry (November 15, 1922). The paper contains a critical discussion of the changes that have been observed in coal and similar substances during the process of carbonisation, and an account of experimental work carried out on the micro-structure of coke and charcoal.

Use has been made of the new knowledge concerning solids and their internal constitution, for which Sir William Bragg is so largely responsible; and, in another direction, of the technique for cutting and studying sections of coal, introduced by Mr. Lomax. A number of specimens for examination were photographed at their natural size, and with different magnifications and illuminations. It was observed how very much the structure of coke was determined by the size of the bubbles blown in the viscous mass during the semi-liquid stages of carbonisation, and even what have hitherto been commonly regarded as the solid vitreous cell-walls of the pores have been shown to be permeated by minute bubbles. Bound up with this is the control of the bubble formation which can be effected by blending coals of different behaviour, and the practical possibilities forthcoming in this way are discussed at some length. It is shown, for example, that the blending of a coal which swells and froths inordinately with another coal of the non-caking variety may be utilised for securing a strong and firm coke with small and evenly distributed pores.

The relevance of work by Messrs. Sutcliffe and Evans on the briquetting of pulverised coals as a preliminary to carbonisation is indicated. It has been claimed by them that the control of structure could be extended almost indefinitely by the briquetting of finely ground coal by pressure as a preliminary to carbonisation. It was by working along such lines that Sutcliffe and Evans were able to produce a material stated to have at least three times the gas-absorbing capacity of the best wood charcoal, and specially suitable for use in gas masks. Sir George Beilby points out that the combustion of these close-grained "pressure" briquettes proceeds definitely from the outer surfaces inwards, showing that the internal circulation of the oxidising gases is much more restricted than in the case of metallurgical coke — which raises an interesting question.

Seventeen figures are used to elucidate the argument of the text. They are all photo-micrographs of coke produced commercially in gas retorts, coke ovens, etc., or in the laboratory under special and controlled conditions. J. W. C.

University and Educational Intelligence.

ABERDEEN.—The Thomson Lecturer for 1923 at the Aberdeen United Free Church College is Prof. J. Arthur Thomson, LL.D., whose subject is "What is Man? The Nature of Man Scientifically Considered."

EDINBURGH.—Mr. G. G. Chisholm, reader in geography, is to retire at the end of September next, in consequence of which the University Court will shortly proceed to appoint a lecturer who will be responsible for, and in charge of, the teaching of geography in the University. The status of reader may be attached to the office. Applications for the post must reach the Secretary by, at latest, February 28.

THE late Mr. C. T. Milburn, of Newcastle-on-Tyne, bequeathed the sum of 10,000*l.* (in addition to 20,000*l.* given in his lifetime) to Armstrong College, expressing a wish that the legacy should be used for the endowment of a chair for the education of mining engineers or of naval architects, and that his name should be associated with it.

THE annual prize distribution at the Sir John Cass Technical Institute, Aldgate, E.C.3, will be held on Wednesday, January 31, when Sir Thomas Holland, after making the presentations, will deliver an address on "Humanism in Technical Education."

MESSRS. NORTON AND GREGORY, LTD., offer two engineering scholarships to be competed for annually, one of value 100*l.* per annum, and one of value 50*l.* per annum, tenable for three years at any university in the United Kingdom or British Dominions. The honorary committee which will award the scholarships consists of Sir Joseph Petavel (Chairman), Prof. C. E. Inglis (Vice-Chairman), Prof. E. G. Coker, Mr. J. Talbot, Mr. G. H. Burkhardt, and the Chairman and Managing Director of Messrs. Norton and Gregory, Ltd. Candidates must have reached the age of 17 but not the age of 19 on March 1 in the year of examination, be domiciled in the United Kingdom, and undertake to pursue a three years' course in engineering with the view of following it as a profession. Papers, which will cover two days' examination, will be set in English, mathematics, mechanics, and general physics. The main object of the examination will be to prove that candidates have received a good general education on broad lines and not necessarily specialised in engineering. The examination for the 1923 scholarships will be held in March at a date to be fixed later, and all application forms must reach the committee not later than February 15. Official application forms may be obtained from the Secretary, Scholarships Committee, Messrs. Norton and Gregory, Ltd., 1 and 2 Castle Lane, Westminster, London, S.W.1.

Societies and Academies.

LONDON.

The Royal Society, January 18.—Sir Charles Sherrington, president, in the chair.—J. **Barcroft**: Observations on the effect of high altitude on the physiological processes of the human body. Three principal factors appear to have a positive influence in acclimatisation. (*a*) The increase in total ventilation, which usually raises the alveolar oxygen pressure ten or twelve millimetres higher than it would otherwise be; (*b*) The rise in the oxygen dissociation curve so that at any oxygen pressure the hæmoglobin will take up more oxygen than before; (*c*) The rise in the number of red corpuscles, and correspondingly in the quantity of hæmoglobin. These factors are not independent variables. Blood has been found to give, at the alveolar carbon dioxide pressure of the Andes (about 27 mm. carbon dioxide): (1) A reaction which is apparently almost unchanged, or even more acid, as measured by the ratio of combined to free carbon dioxide; (2) A more alkaline reaction by the platinum electrode; (3) An oxygen dissociation curve which rises apparently out of proportion to the change in reaction. On making the ascent, there was a marked increase in the number of reticulated red cells; after the descent these cells fell to below their normal percentage. In the natives the ratio of reticulated to unreticulated red cells was not greatly increased, but the absolute number of reticulated cells per cubic millimetre was about 50 per cent. greater than normal. We argue a hypertrophy in the bone marrow. There were no nucleated red cells. The increase in red blood corpuscles is such as to cause an absolute increase in the amount of oxygen in each cubic centimetre of blood in the majority of cases, in spite of the decrease in saturation. A number of mental tests of the ordinary type were performed at Cerro and at sea-level. These revealed no particular mental disability. The pressure of oxygen in the blood was so nearly the same as that in the alveolar air that we attribute the passage of gas through the pulmonary epithelium to diffusion.—E. W. **MacBride**: Remarks on the inheritance of acquired characters. During the last fifteen or twenty years a series of experiments have been carried out by Dr. Paul Kammerer at Vienna, which tend to show that acquired qualities, or, in other words, modifications of structure induced by modified habits, are inheritable. One of the most interesting of his experiments was to induce Alytes, a toad which normally breeds on land, to breed in water. As a result, after two generations, the male Alytes developed a horny pad on the hand, to enable him to grasp his slippery partner. Mr. J. Quastel, of Trinity College, Cambridge, when in Vienna, saw and photographed one of these modified males; the animal has also been seen by Mr. E. Boulenger.—C. F. **Cooper**: *Baluchitherium osborni* (? syn. *Indricotherium turgaicum*, Borrissyak). *Baluchitherium osborni* is an aberrant rhinoceros, apparently the largest known land mammal. The remains were first found in Baluchistan. Further fragments have been found in Turkestan, and, recently, in China. While resembling the rhinoceroses more than any other of the Perissodactyla, Baluchitherium is still isolated and of uncertain zoological position. Adaptations to weight have brought about a superficial resemblance to the limb bones of elephants. Some of the foot bones and neck vertebræ resemble those of the horse; due possibly to descent from a small eocene form, Triplopus, which likewise shows an intermingling of horse and rhinoceros characters. In some structures, notably the excavations of the vertebral canal to ensure a combination of lightness and strength, Baluchitherium stands alone among mammals.—J. A. **Gunn** and K. J. **Franklin**: The sympathetic innervation of the vagina.—H. G. **Cannon**: On the metabolic gradient of the frog's egg.—Basiswar **Sen**: On the relation between permeability variation and plant movements.—H. L. **Duke**: An inquiry into an outbreak of human trypanosomiasis in a *Glossina morsitans* belt to the East of Mwanza, Tanganyika Territory.—Louis **Dollo**: Le Centenaire des Iguanodons (1822–1922).

Geological Society, December 20.—Prof. A. C. Seward, president, in the chair.—W. A. **Richardson**: A micrometric study of the St. Austell granite (Cornwall). The problem of the effect of sampling a coarse-grained rock by means of slices is considered in detail. Qualitative and quantitative study of the minerals reveals three types of rock: (*a*) a biotite-muscovite-granite of coarse grain confined to the east: (*b*) a lithionite-granite occupying by far the greater part of the outcrop; and (*c*) a gilbertite-granite confined to a small area near St. Stephen's Beacon, and furnishing the "china-stone" rock. A high negative correlation is found between quartz and orthoclase—true for this area, but not for granites in general. When mapped, the minerals fall into groups that are distinctly connected with the areas occupied by the different types, and in each of which there is an outer zone rich in quartz surrounding an inner region with a high content of orthoclase. The magma probably invaded the area progressively from the east to the west; it had always partly crystallised before injection into the present level.—W. G. St. J. **Shannon**: The petrography and correlation of the igneous rocks of the Torquay promontory. Two stages of vulcanicity occurred—in the Middle and in the Upper Devonian, as shown by basic tuffs and a spilite. The intrusions form an alkaline suite. An augite-lamprophyre in limestone, and a soda-porphyrite in Middle Devonian slates are described from Babbacombe. A preliminary account of the tectonics is attempted, particularly of the inversion, at Ilsham, of the faulting and of the north-to-south strike of some of the folds.

Aristotelian Society, January 8.—Prof. T. P. Nunn in the chair.—W. Adams **Brown**: The problem of classification in religion. The differences in existing religions may be explained in three different ways. They may be regarded, as variations from a single standard type; as moments in the development of one all-embracing religion; or as recurrent parallel contrasted types. If the last view be taken, the principle of classification may be found in the variations of the individual personal experience, or in differences in man's social attitude. Most recent study of religious types has followed the first of these methods. This method, helpful so far as it goes, can be usefully supplemented by an analysis of man's social relationships. The new classification is based upon the attitude of religious people to social institutions. There are three possible attitudes which one may take towards the existing social order. One may accept it as it is without question and yield its institutions willing and loyal allegiance. One may protest against it as corrupt or negligible and find in one's own inner life a sufficient refuge and compensation. One may believe that society is itself in process of being transformed into new and better forms and that each man and woman may have part in that remaking. These three attitudes have their counterpart in religion. One man believes that he communes with God most

perfectly through allegiance to some existing organisation the triumph of which in the world he identifies with the victory of God's will. Another believes that he communes with God most deeply when he withdraws his attention from all that is finite and transitory, and concentrates it upon the attempt to realise the immediate presence of God. A third is persuaded that he communes with God most truly as he joins his fellows in remaking the institutions of society (including the church itself) according to a constantly clearer apprehension of the will of God, as that will is being progressively revealed to all who seek it in humility and faith. These three types may be designated imperialism, individualism, and democracy. Each has given rise to institutions appropriate to its genius.

Mineralogical Society, January 9.—Dr. A. E. H. Tutton, past-president, in the chair.—A. **Brammall** and H. F. **Harwood**: Dartmoor occurrences of (1) rutile, brookite, and anatase; (2) zircon. (1) Anatase, with less abundant brookite and scanty rutile, is common in Dartmoor stream-sands, etc. Anatase and brookite, absent from the unaltered grey granite, have been found in pneumatolysed rocks, especially "red" granites, and the mode of genesis of these two minerals is discussed. Data provided by chemical work on "baueritised" Dartmoor biotite (containing about 1·8 per cent. TiO_2) and by the occurrence of anatase granules encrusting detrital grains of ilmenite are examined in their bearing on the possibility that some anatase may have developed (or existing crystals may have continued to grow) in detrital material after sedimentation. (2) Two strongly contrasted kinds of zircon crystals are described: differences in crystal habit, nature of inclusions, and mode of occurrence in the granite suggest that the dominant kind, which is tawny, zoned, and rich in inclusions, crystallised out from the magma early, and that the subordinate kind, water-clear, and containing few inclusions, separated out at a much later stage.—Dr. L. J. **Spencer**, with chemical analyses by E. D. **Mountain** and microscopical determinations of the pseudomorphs by W. Campbell **Smith**: A davyne-like mineral and its pseudomorphs from St. John's Island, Egypt. Two small crystals found with peridot, garnierite, etc., showed the physical characters of davyne, but consist of a complex silicate (with sulphate and carbonate) of aluminium, calcium, magnesium, and sodium, together with a considerable amount of water. Pseudomorphs after this material are more abundant; they consist of a complex of hydrated silicates of aluminium and magnesium together with small amounts of corundum and spinel.

Royal Meteorological Society, January 17.—Dr. C. Chree, president, in the chair.—C. **Chree**: Aurora and allied phenomena. Brilliant aurora in England seems always to be accompanied by a magnetic storm, and any outstanding magnetic disturbance is accompanied by aurora. Thus presumably they have a common cause, now generally believed to be electrical currents in the upper atmosphere, originated by a discharge of some kind from the sun. Our knowledge of the height of aurora is mainly due to Norwegian men of science. Prof. Carl Störmer discovered how to photograph aurora, and by taking simultaneous photographs from the ends of a long base, and measuring the apparent parallax, he is able to calculate the height. For the lower level of aurora he finds heights in the neighbourhood of 100 kilometres. The height of the highest visible appearance varies greatly. Heights exceeding 300 kilometres are not very uncommon, and some measurements have exceeded 600 kilometres. Travelling northwards from the south of England, aurora and magnetic disturbances both increase, the former at least very rapidly. The auroral frequency in Shetland is said to be 10 to 20 times that in the extreme south of England. There is thus within the British Isles a great variety in the frequency or intensity of aurora, and it is also believed in the intensity of magnetic disturbance. An observatory provided with magnetographs has recently been established in Shetland, and if adequate means are forthcoming for the intensive study of auroral and magnetic phenomena, substantial contributions to knowledge may reasonably be expected.

PARIS.

Academy of Sciences, January 3.—M. Albin Haller in the chair.—The president announced the death of Gaston Bonnier, member of the section of botany.—R. **de Forcrand**: The alcoholates of thallium. Thallium differs from sodium and potassium in that it does not displace hydrogen directly from the alcohols. Alcohol vapour acts upon thallium in the presence of oxygen, giving the compound $C_2H_5.OTl$ as a dense oily liquid (density 3·55). This liquid added to an excess of anhydrous methyl alcohol gives thallium methylate, $CH_3.OTl$, as a solid. With the same thallium ethylate as the starting point, corresponding compounds have been prepared from glycol, glycerol, and phenol.—Paul **Vuillemin**: The classification of the monocotyledons.—Bertrand **Gambier**: The curves of Bertrand.—Stanislas **Millot**: Probability *a posteriori*.—J. **Haag**: The study of certain problems in kinetic theory, with the hypothesis that the intermolecular force is some function of the distance.—Margaret G. **Tomkinson**: The catalytic hydrogenation of sulphur dioxide. A mixture of dry hydrogen and sulphur dioxide in the presence of reduced nickel at about 400° C. gives water, sulphuretted hydrogen, and sulphur. The nickel is wholly converted into nickel sulphide, but in spite of this, the catalytic reduction can be carried on indefinitely.—A. **Mailhe**: The catalytic decomposition of castor oil. The oil was decomposed by passing over alumina and metallic copper at 550° to 570° C. The gaseous products contained 36 per cent. of unsaturated hydrocarbons: from the liquid portion oenanthylic aldehyde, hexane, and heptane were isolated. At temperatures above 600° C. aromatic hydrocarbons were also identified.—Mme. A. **Hee**: Study of the Algerian earthquake of August 25, 1922, from the microseismic observations. A discussion of the seismographs from eight observatories. The epicentre was deduced from these to be near Cavaignac, and this is in agreement with the macroseismic observations.—Emmanuel **de Martonne**: The Pliocene delta of the Var and the erosion levels of the valleys opening into it.

SYDNEY.

Linnean Society of New South Wales, November 29.—Mr. G. A. Waterhouse, president, in the chair.—J. **Mitchell**: Descriptions of two new trilobites and note on *Griffithides convexicaudatus* Mitch. A species of Cordania is described from Australia for the first time. A new species of Ptychoparia forms an addition to the fossil fauna of North-west Queensland. *Griffithides convexicaudatus* Mitchell is transferred to the genus Phillipsia.—Marguerite **Henry**: A monograph of the freshwater Entomostraca of New South Wales. Pt. ii. Copepoda. Twenty-three species of copepods, one of which is recorded for the first time in Australia, four for the first time in New South Wales and three which are new, are described. Two

of these species belong to the division Harpacticoida.—C. P. **Alexander**: New or little known species of Australian Tipulidæ (Diptera), Pt. i. An account of twenty-three specimens from a number of Australian collections.—H. S. Halcro **Wardlaw**: The effect of suspended respiration on the composition of alveolar air. Inspirations were held in the lungs until the composition of the alveolar air ceased to alter. Circulatory disturbances were minimised by holding an inspiration for a number of consecutive short periods instead of for one long period. Similar final values were reached whether the initial inspiration consisted of air alone or of air mixed with a percentage of carbon dioxide higher than the normal alveolar percentage. Similar final values were reached also whether the inspiration was held under normal or under negative intrathoracic pressure; this was not the case when circulatory disturbances were allowed to exert their effect.—A. M. **Lea**: On Australian Anthicidæ (Coleoptera). Notes on synonymy, variation, and distribution are given, and 53 species are described as new.—J. **McLuckie**: A contribution to the parasitism of *Notothixos incanus* (Oliv.) var. *subaureus*. The structure of the fruit, the mechanism of seed-dispersal, the structure of the haustorium and its relation to the host-tissues, are described.—T. Thomson **Flynn**: The phylogenetic significance of the marsupial allantoplacenta. In a typical mammal, the placental cycle is divisible into three stages,—metrioplacental, omphaloplacental, and allantoplacental. The last stage is absent in all marsupials except Perameles. Examination of the allantoplacenta of Perameles shows its definite relation to that of Monodelphia. It is considered that the ancestors of marsupials were, therefore, placental.

Official Publications Received.

The Institution of Civil Engineers. Engineering Abstracts prepared from the Current Periodical Literature of Engineering and Applied Science, published outside the United Kingdom. New Series, No. 14, January. Edited by W. F. Spear. Pp. 186. (London: Gt. George Street.)

Agricultural Research Institute, Pusa. Bulletin No. 136: The Hydrogen Ion Concentrations of some Indian Soils and Plant Juices. By Dr. W. R. G. Atkins. Pp. ii+12. Bulletin No. 137: Note on the Probability of an Inter-relation between the Length of the Stigma and that of the Fibre in some forms of the genus Gossypium. By Ram Prasad. Pp. ii+7+2 plates. (Calcutta: Government Publications Office.) 4 annas each.

Schriften der Naturforschenden Gesellschaft in Danzig. Neue Folge. Fünfzehnten Bandes Drittes und Viertes Heft. Teil 2: Jahresbericht für 1921. Pp. ii+55. Teil 3: Wissenschaftliche Abhandlungen. Pp. viii+112. (Danzig).

44 Bericht des Westpreussischen Botanisch-Zoologischen Vereins. Pp. iv+30. (Danzig).

Geological Literature added to the Geological Society's Library during the Year ended December 31st, 1914. Compiled by Arthur Greig. Pp. iv+193. (London: Geological Society.) 5s.; 3s. 9d. to F.G.S.

Hampstead Scientific Society. Report of the Council and Proceedings, with a List of the Members, for the Period October 1920 to September 1922; with Reports of General Meetings, 1919-1920. Pp. 63. (London: Stanfield House, Prince Arthur Road.)

Diary of Societies.

SATURDAY, JANUARY 27.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Walford Davies: Speech Rhythm in Vocal Music (2).

MONDAY, JANUARY 29.

BRITISH PSYCHOLOGICAL SOCIETY (Æsthetics Section) (at Bedford College for Women), at 4.30.—L. Abercrombie: Communication *versus* Expression.

INSTITUTE OF ACTUARIES, at 5.—W. Palin Elderton: Notes on the Treatment of Extra Risk.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. R. L. Knaggs: Osteitis Fibrosa.

ROYAL SANITARY INSTITUTE, at 5.30.—Dr. L. C. Parkes: Introductory Lecture to Students in the various Courses.

ARISTOTELIAN SOCIETY (at University of London Club), at 8.—Prof. W. A. Brown: The Problem of Classification in Religion.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Capt. J. E. T. Phillips: Kigezi and the Birunga Range, Uganda.

TUESDAY, JANUARY 30.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—R. D. Oldham: The Character and Cause of Earthquakes (1).

INSTITUTE OF MARINE ENGINEERS, INC., at 6.30.—A. Keens: Some Deductions from Indicator Diagrams.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—T. Bell: On the Thames with a Camera.

WEDNESDAY, JANUARY 31.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. M. Woodman: Malignant Disease of the Upper Jaw, with special reference to Operative Technique.

INSTITUTION OF MECHANICAL ENGINEERS (Students' Meeting), at 6.—T. R. Wilton: Foundations in Dock and Harbour Works (Vernon-Harcourt Lectures) (2).

ROYAL SOCIETY OF ARTS, at 8.—T. H. Fairbrother and Dr. A. Renshaw: The Relation between Chemical and Antiseptic Action in the Coal Tar Dyes.

ROYAL SOCIETY OF MEDICINE (Social Evening), at 9.—Prof. W. Wright: Leonardo da Vinci.

THURSDAY, FEBRUARY 1.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. I. M. Heilbron: The Photosynthesis of Plant Products (1).

ROYAL SOCIETY, at 4.30.—Prof. O. W. Richardson: The Magnitude of the Gyromagnetic Ratio.—Sir Richard Paget: The Production of Artificial Vowel Sounds.—F. Simeon: The Carbon Arc Spectrum in the Extreme Ultra-violet.—Prof. J. Joly: Pleochroic Haloes of various Geological Ages.—Prof. H. A. Wilson: The Motion of Electrons in Gases.—Dr. H. Hartridge: The Coincidence Method for the Wave-length Measurement of Absorption Bands.—A. Berry and Lorna M. Swain: The Steady Motion of a Cylinder through Infinite Viscous Fluid.—W. Jevons: The Line Spectrum of Chlorine in the Ultra-violet (Region λ 3354-2070 A).—M. H. Evans and H. J. George: Note on the Adsorption of Gases by Solids and the Thickness of the Adsorbed Layer.

LINNEAN SOCIETY OF LONDON, at 5.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 5.30.—G. S. Baker: Ten Years' Testing of Model Seaplanes.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—P. J. Robinson: The Maintenance of Voltage on a D.C. Distribution System by means of a fully Automatic Substation.

CHEMICAL SOCIETY, at 8.

ROYAL SOCIETY OF MEDICINE (Obstetrics and Gynæcology Section), at 8. Dr. W. R. White-Cooper and H. K. Griffith: (1) A Case of Inversion of the Uterus occurring in the Third Week of the Puerperium; (2) A Case of Obstructed Labour due to Contraction Ring.—B. Whitehouse and Dr. H. Featherstone: Note on the Use of Spinal Anæsthesia with Tropococaine in cases of Cæsarian Section.—Dr. S. Cameron: Cæsarian Section.

CAMERA CLUB, at 8.15.—J. E. Saunders: Off the Beaten Track at the Zoo.

FRIDAY, FEBRUARY 2.

ROYAL SOCIETY OF MEDICINE, (Laryngology Section), at 4.45.—Dr. I. Moore: Operative Procedures in the Treatment of Bilateral Paralysis of the Abductor Muscles of the Larynx, with Special Reference to a New Method by means of which, it is suggested, the Air-way may be Re-opened and the Patient Decannulated.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. C. A. Joll: The Metatastic Tumours of Bone.

ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion), at 5.—Col. E. M. Jack: The Projection for the International Aeronautical Map. Other speakers, Capt. G. T. McCaw, Col. Sir C. F. Close, Col. J. L. Winterbotham, and probably A. R. Hinks. Chairman, Sir G. P. Lenox-Conyngham.

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—A. E. L. Chorlton: The Use of Light Alloys in place of Iron and Steel.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—P. J. Waldram: Ventilation and Lighting of Factories.

ROYAL SOCIETY OF MEDICINE (Epidemiology and State Medicine Section), at 8.—Dr. R. J. Reece: Progress and Problems in Epidemiology (Presidential Address).

ROYAL SOCIETY OF MEDICINE (Anæsthetics Section), at 8.30—Dr. J. S. Goodall: Some Cardiovascular Conditions in relation to Anæsthesia.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—C. F. Cross: Fact and Phantasy in Industrial Science.

PUBLIC LECTURES.

SATURDAY, JANUARY 27.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Capt. W. H. Date: Wireless Telephony and Broadcasting.

TUESDAY, JANUARY 30.

GRESHAM COLLEGE, at 6.—A. R. Hinks: Astronomy. (Succeeding Lectures on January 31, February 1 and 2).

WEDNESDAY, JANUARY 31.

KING'S COLLEGE, at 5.30.—Sir Frank Dyson: The Measurement of Stellar Distances.

THURSDAY, FEBRUARY 1.

FINSBURY TECHNICAL COLLEGE (Leonard Street), at 7.30.—Sir Oliver Lodge: The Basis of Wireless Communication (Silvanus Thompson Memorial Lecture).

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—G. T. Forrest: London's Unhealthy Areas (Chadwick Lectures (1)). (Succeeding Lecture on February 8).

SATURDAY, FEBRUARY 3.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—F. Balfour-Browne: Insect Pests and their Control.

THERESA SEESSEL RESEARCH FELLOWSHIP

To promote Original Research in Biological Studies.

YALE UNIVERSITY.

One FELLOWSHIP, yielding an income of $1500. Preference is given to candidates who have already obtained their Doctorate, and have demonstrated by their work fitness to carry on successfully original research of a high order. The holder must reside in New Haven during the college year, October to June. Applications should be made to the DEAN of the GRADUATE SCHOOL, New Haven, Conn., before May 1, 1923; they should be accompanied by reprints of scientific publications, letters of recommendation, and a statement of the particular problem which the candidate expects to investigate.

EMIL CHR. HANSEN PRIZE, 1923.

Under the Fund provided by the late Professor EMIL CHR. HANSEN and his wife, a Gold Medal bearing an effigy of Prof. Hansen, accompanied by a sum of at least 2000 kroner, is awarded at intervals of two or three years, on his birthday, May 8.

It is proposed to award the Medal this year to an author of

EXPERIMENTAL RESEARCHES IN MARINE MICROBIOLOGY.

The Prize is open to scientific workers of all countries. Committee of award for 1923:

Prof. C. O. JENSEN, Veterinary and Agricultural College, Copenhagen.
Dr. JOHS. SCHMIDT, Carlsberg Laboratory, Copenhagen.
Prof. S. P. L. SÖRENSEN, Carlsberg Laboratory, Copenhagen.
Prof. H. H. GRAN, University of Christiania, Norway.
Prof. C. A. KOFOID, University of California, Berkeley, U.S.A.

For further particulars, apply to THE PRESIDENT, Board of Trustees, Emil Chr. Hansen Fund, Copenhagen, Valby.

RESEARCH FELLOWSHIPS IN ACOUSTICS.

THE RIVERBANK LABORATORIES AT GENEVA, ILLINOIS, announce the establishment of one or two RESEARCH FELLOWSHIPS in ACOUSTICS. The holder will have an opportunity to devote his entire time to study and investigation in a laboratory built, equipped, and manned for the study of acoustic problems. Candidates should be college graduates who have taken advanced courses in physics and mathematics, and who have shown in their work those qualities essential for success in independent investigation. Terms of appointment to be determined by the qualifications of the appointee. Address, B. CUMMING, Secretary, Geneva, Illinois.

THE MURDOCH TRUST.

For the benefit of INDIGENT BACHELORS and WIDOWERS of Good Character, over 55 years of age, who have done "something" in the way of Promoting or Helping some branch of Science.

Donations or Pensions may be granted to persons who comply with those conditions.

For Particulars apply to Messrs J. and J. TURNBULL, W.S., 58 Frederick Street, Edinburgh.

CHELSEA POLYTECHNIC,

CHELSEA, S.W.3.

Day and Evening Courses in Science under Recognised Teachers of London University.

I. **INDUSTRIAL CHEMISTRY DEPARTMENT.** Technical Courses in Analytical and Manufacturing Chemistry, Pharmacy, Food and Drugs, A.I.C. Courses, Metallurgy, Assaying, Foundry Work, Research.

II. **INDUSTRIAL PHYSICS DEPARTMENT.** Practical work in General Physics, Applications to Industries, Metrology, Calorimetry, Illumination, Acoustics, Electrical Measurement, Research.

III. **BIOLOGICAL AND GEOLOGICAL DEPARTMENT.** Courses for B.Sc., etc., in Botany, Geology, Mineralogy, Zoology, Special Courses in Bio-chemistry, Bio-physics, Bacteriology, Physiology, Hygiene, Entomology, Plant Pathology. Course for Tropical Planters, Research.

Lent Term began on January 9, 1923.

SIDNEY SKINNER, M.A.
Principal.

Telephone: Kensington 809.

BIRKBECK COLLEGE.

(UNIVERSITY OF LONDON.)

Principal—GEORGE SENTER, D.Sc., Ph.D., F.I.C.

EVENING COURSES for the Degrees of the University of London in the Faculty of Science and for the Geography Diploma.

Facilities are also provided during both day and evening for Post-Graduate and Research Work.

Calendar, 1s.; by post, 1s. 5d. Prospectus free.

For full particulars, apply to the SECRETARY, Birkbeck College, Fetter Lane, E.C.4.

BATTERSEA POLYTECHNIC.

LONDON, S.W.11.

Principal—ROBERT H. PICKARD, D.Sc., F.R.S.

Full-time day courses in Engineering (Mechanical, Civil and Electrical), Chemistry, Flour Milling, Physics, Mathematics.

Students prepared for University of London Internal Degrees, A.I.C. Examination, and Polytechnic Diplomas.

Evening courses in Engineering, Chemistry, Physics, Mathematics, and Music in preparation for Internal Degrees in the Faculties of Science, Engineering and Music.

Library, Writing Room, Common Rooms, Refreshment Rooms, large Athletic Ground, etc.

Particulars on application to the PRINCIPAL.

APPOINTMENTS BOARD

OF THE

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY,

SOUTH KENSINGTON, S.W.7.

EMPLOYERS requiring men who have received a thorough training in Science and Technology, and who are Diplomates or Associates of the Imperial College, or of one of its three constituent Colleges, are asked to make use of the services of the Board. No fees.

The Imperial College includes The Royal College of Science, The Royal School of Mines, and The City and Guilds (Engineering) Colle . The Associates of the Colleges receive thorough training in Science ar ch-nology, including Aeronautics, Applied Optics and Optical Eng eering Biology, Chemical Technology, Chemistry (all branches), Enginee ing (all branches, including Metallurgy, Mining, Mining Geology and Oil Technology), Geology, Mathematics and Mechanics, and Physics.

NO. 2779, VOL. 111]

The Science and Practice of Pure Milk Supply.

II.

IN last week's article on this subject emphasis was placed on the importance of the consideration that efforts to secure pure milk satisfying scientific conditions should not, if possible, be permitted to reduce the total quantity of milk available for public use. There is little doubt that immediate action to enforce the supply of milk from non-tuberculous cattle would have this effect, and thus action beneficent in its intention would be inimical to the public welfare.

There is every reason for excluding from milking herds all cows with diseased udders, or which can be shown to be giving milk containing tubercle bacilli. It is advisable to encourage farmers to clear their herds of tuberculosis, and to give special certificates to farmers who sell milk only from cows proved free from tuberculosis by the tuberculin test. It may be desirable to go further than this for small herds of cattle, with a limited supply; for a single diseased cow in a small herd is much more dangerous to human consumers than when the bacillary milk is diluted in a vaster volume of milk. There are those who regard the imbibition of small quantities of tubercle bacilli in milk as a valuable means of securing partial human immunity; but even if this be accepted as possible, the toleration implied by it of tuberculous infection of unknown dosage is unscientific, and the only sensible plan is to pasteurise milk from untested herds. Every human being receives tubercle bacilli of human origin in small doses, and the prevention of human tuberculosis may be said to consist—on the side of infection—in preventing too frequent or massive infection, beyond the powers of personal resistance. This is much more important for young children than for adults, whether the tuberculous infection is derived from milk or from a consumptive human patient,

Pasteurisation then is a chief means of protection against the occasional dangers of milk. It is not an alternative to the hygiene of the cow and of the cow-shed, of transport, of sale, and of domestic storage. It is supplementary to them and aids their action. Nor can pasteurisation be said to encourage the continuance of a dirty milk supply. Milk which is dirty does not keep well after pasteurisation, and is thus commercially unprofitable. The methods of pasteurisation have improved, the flash method having been replaced by the "holder method" of pasteurisation, which makes it more likely that the milk will all be subjected to the temperature decided upon. Pasteurisation is still in process of improvement, as there is reason to think that in practice

some of the milk may escape too soon from the heating process. Even so the danger of tuberculosis, etc. has been greatly reduced, for dosage of infection is an essential element in the result. The temperature prescribed in the recent Order of the Ministry of Health is not less than 145° F. and not more than 150° F. for at least half an hour, the milk to be immediately cooled to a temperature of not more than 55° F. It is also laid down that any sample of pasteurised milk taken before delivery to the consumer shall not contain more than 30,000 bacteria per c.c. nor any bacillus coli in one-tenth of a cubic centimetre.

It is unfortunate that, in the somewhat hesitating and tentative regulations of the Ministry of Health, it has not been regarded as advisable to regulate the conditions of commercial pasteurisation, which is practised on a large scale without any special certificate being asked for by the producer. It is probable that at the present time most of the milk coming into London is pasteurised, though not always satisfactorily. In American cities such pasteurisation is subject to rigid supervision, an automatic gauge of the temperature of pasteurisation being kept for official inspection: and the system now inaugurated in England, in which it will be possible for vendors to pay for a certificate of permission to sell "pasteurised" milk, while their neighbours are selling pasteurised or partially pasteurised milk without such a certificate and without disclosure of the fact that the milk has been treated by heat, is obviously a system which should not continue. The uncertified and undeclared pasteurisation has real possibilities of mischief; for it leads the unsuspecting purchaser to subject the milk to repeated heating to its detriment. Such doubly-heated milk is liable to produce scurvy and rickets. This naturally leads to the consideration of the drawbacks to pasteurisation of milk. The evidence goes to show that pasteurisation as defined above, followed by rapid cooling, does not spoil the milk. Such milk, like dried milk, has not been shown to produce scurvy: and any fear on this point is averted by the use of fruit juice in small quantities. Although the vitamin-content of milk treated on the "holder" system has not been adequately investigated, experimental observations quoted in the October issue of the *Scottish Journal of Agriculture* show that there need be little apprehension on this head, especially if the precautionary use of fruit juice is adopted. The admirable results of feeding infants on dried milk confirm this opinion.

The general enforcement of pasteurisation of milk is called for in the public interest, and there can be little doubt that step by step this will come into operation. It is the most practical method of State regulation; and it secures immediate safety against serious risks of infection when carried out satisfactorily. For many years efforts to improve the sanitary conditions of the farm and the cow-byre have been made, but with results which are quite incommensurate with the expense involved. By dirt tests, bacterial counts, insistence on cooling of the milk at the farm, and allied measures, both the wholesale purchaser of the farmer's milk and the sanitary authority can do much to increase its cleanliness; but pasteurisation is the essential safeguard in the public interest. Attacks on pasteurised milk are not justified scientifically, and they imply, if successful, a continuance of the supply of infective milk, with the dangers at present associated with its consumption. Pasteurisation is already enforced in a considerable number of American cities, and we would welcome action on the part of the British Government which would permit large local authorities in this country to aid the milk industry and to safeguard the public health by enforcing the pasteurisation under satisfactory conditions of the local milk supply.

The pasteurisation of milk supplies carries with it the distribution of milk in sterilised sealed bottles, which is an important safeguard against domestic contamination, a chief source under present conditions of mischief.

The Ministry of Health has issued regulations also as to superior qualities of milk, which may be described as Certified, Grade A or Grade A (tuberculin tested). Grade A milk is described in the official notice circulated with these regulations as "superior to the ordinary milk of the country and reasonably safe under all ordinary circumstances." Evidently certification of such milk must be made with fear and trembling. According to the schedule of conditions imposed, the cows have not been proved to be free from tuberculosis by the tuberculin test, the chief test imposed being a trimestrial examination of the herd by a veterinary surgeon, who orders the exclusion of any animal "showing evidence of any disease which is likely to affect the milk injuriously." American experience has shown that even with tuberculin testing, it is necessary to pasteurise the Grade A milk supplied for children's hospitals: and the above certificate for Grade A milk cannot be regarded as conferring anything approximating to the security for the consumer which efficient pasteurisation provides. The above-quoted definition conduces to furious thought. We must regard the "ordinary milk of the country"—the milk with which the vast majority of children are supplied—as not "reasonably safe." If so, and it is so, why does the Ministry of Health stop short of a simple regulation requiring

pasteurisation of the mass of publicly supplied milk and thus at once ensuring safety from the chief dangers of our milk supply? Why also does it not insist on declaration of pasteurisation when this has been done commercially apart from any regulations for certifying pasteurised milk?

Physics and Psychics.

(1) (*Psychical Research*). *The Goligher Circle, May to August 1921.* Experiences of Dr. E. E. Fournier d'Albe. With an Appendix containing Extracts from the Correspondence of the late Dr. W. J. Crawford, and others. Pp. 81 + plates. (London: J. M. Watkins, 21 Cecil Court, 1922.) 7s. 6d. net.

(2) *The Case against Spirit Photographs.* By C. Vincent Patrick and W. Whately Smith. Pp. 47. (London: Kegan Paul and Co., Ltd., 1922.)

(3) *Cold Light on Spiritualistic "Phenomena": An Experiment with the Crewe Circle.* By Harry Price. Pp. 15. (London: Kegan Paul and Co., Ltd., 1922.) 6d. net.

(1) IN this book Dr. Fournier d'Albe records his experiments with the Goligher medium and Circle, undertaken to corroborate, if possible, the remarkable results claimed by the late Dr. Crawford. In order to explain certain alleged occult phenomena ("raps," "levitations," etc.) obtained with this medium, Dr. Crawford postulated as the agents invisible entities which he called "operators," and believed to be departed human beings (spirits). The *modus operandi* of the "operators" is as follows: From the medium's body, metamorphosed from her "flesh," a substance, indifferently called "plasm," "ectoplasm," "psychic fluid," etc., emanates as an extensible rod, the proximal end of which retains connexion with the medium's body, the distal free end being provided with a "suction grip" to hold, and move, objects. Dr. Crawford not only photographed this "psychic stuff," but also in June 1920 *saw* it and *felt* it wriggling up the medium's legs like a snake. Shortly after this experience he committed suicide, and his researches ceased. Some ten months later Dr. Fournier d'Albe takes up the broken threads. The séance room he describes as feebly illuminated by a one candle-power gas-burner, enclosed in a box with red glass sides so arranged that the medium is in comparative darkness, the floor, the legs of the members of the Circle, and even some of their hands, being in total darkness. Kathleen Goligher, the medium, is seated at one end, so to speak, of the circle of sitters, her father being almost invariably next her.

Dr. Fournier d'Albe placed at the bottom of an empty decanter a glass button, a peg, and a cork, and asked the "spirits" to remove the cork by means of a "psychic structure," but leave the other objects in the decanter. The "spirits," apparently unable to discriminate between the objects, remove the button. Dr. Fournier d'Albe next placed with the button a drop of mercury in the decanter, and requested the "spirits" to remove the former only. After repeated attempts they gave it up, saying, through raps, that they would try again another day. They did—and succeeded. Lastly, to prevent both inversion of the decanter and substitution, Dr. Fournier d'Albe asks them to remove the button from a decanter containing water. After several trials the "spirits" rap out the message that they cannot do so, as the water dissolves the "psychic structure."

By this time the experimenter is becoming disillusioned. Nor are his suspicions allayed by the chiffon-like appearance of the shadowgraph which he took of the "ectoplasm." Finally, when Dr. Fournier d'Albe unmistakably felt muscular movements of both father and daughter going on in unison with the movements of a "levitated" table, when, a little later, he saw a "levitated" stool balanced on the foot of the medium's outstretched leg, he thought it time to conclude the experiments. He sent the medium a cheque, stating he desired no more sittings as, after three months' experimenting, he had gathered no definite evidence in favour of the psychic origin of the phenomena. However, he was persuaded to attend one more sitting at which a great effort was to be made to produce evidential phenomena. Dr. Fournier d'Albe assented, stipulating that the medium's feet be tied to the chair, and her arms held. This was agreed to, but, as is always the case at séances when trickery is precluded, there were no spiritualistic phenomena of any kind, no levitation could be obtained—not even the faintest rap.

Dr. Fournier d'Albe is to be congratulated on his exposure of this notorious medium and Circle. But let the reader be under no misapprehension: although Dr. Fournier d'Albe says Dr. Crawford's experiments are invalidated he yet sees nothing in his own dealings with the Golighers to make him doubt the genuineness of the "spiritualistic phenomena" of Madame Bisson and her medium Eva C. We wonder if he holds the same opinion now that the "phenomena" of this French medium have been dismissed as a "clumsy hoax" by a committee of professors who recently witnessed them.

The book contains an appendix dealing with the correspondence of the late Dr. Crawford and others which the reader cannot afford to ignore, as it furnishes a good insight into the reasoning capacity and "scientific method" of spiritualists.

(2) The authors describe the many methods of taking spirit-photographs, enumerate the devices of mediums for deceiving the public, and, finally, state why they decline to accept the phenomena as genuine. "Of all spiritualistic phenomena," says Mr. Smith, "spirit-photographs are the most obviously fraudulent."

The general argument of believers in spirit-photography is as follows: The ether waves that affect the eye (light) constitute but a small proportion of the complete wave-scale. The photographic plate is sensitive to infra-red and ultra-violet waves, and to X-rays, to all of which the retina is indifferent. Why, therefore, should not the photographic plate respond to "spirit" emanations? The reasoning, while not altogether unsound, calls to mind the advice in the cookery book in the recipe for hare soup—first catch your hare!

The type of spirit-photograph with which this work principally deals is, in the jargon of the cult, an "extra." A bereaved individual gives the spirit-photographer (medium) a description or a portrait of the departed one from whom he wants a sign. After payment of fees he sits for his portrait, which is duly presented with an extra figure thereon that the victim imagines to represent his lost one. Spiritualists claim that hundreds of "extras" have thus been recognised, which only shows how much the psychology of deception accentuates the truism—the wish is father to the thought. The spirit-photographer Buguet was eventually detected and sentenced to twelve months' imprisonment and a heavy fine; yet, despite his confession of guilt and his description of how he had faked the "spirits" on his photographs, witness after witness came forward and swore to having recognised the "extras."

Mr. Patrick, in a careful analysis of "Fairy Photographs," recently published by Sir A. Conan Doyle, directs attention to the many suspicious points demanding further explanation, and he does not hesitate to label the fairies as "fakes."

If only those who desire to receive communications from the unseen would first read this book one of the most pernicious forms of parasitism extant would disappear.

(3) Mr. Price's remarks are significant, as he is a member of the Society for Psychical Research—a society not notoriously addicted to hypercriticism of occult phenomena. To him is due the credit of exposing Mr. Hope of Crewe, the last and most elusive of the three leading British spirit-photographers. Vearncombe had been detected substituting plates. Mrs. Deane, a member of, and strongly recommended by, the "British College of Psychic Science," has also been proved to have tampered with plates. Remained only Mr. Hope and his assistant Mrs. Buxton. To him comes Mr. Price craving a "spirit extra," and armed with a set of four plates secretly marked by X-rays with a stencil design in such way that, *after development*, the whole set of plates would show the complete design, any lacunæ in the latter proving substitution. As a result, Mr. Hope is found "guilty of deliberately substituting his own plates for those of a sitter."

The question which the reader will ask after perusal of these three works is not—Why are there so many deceivers? but Why are there so many dupes? Money—whether fees for "extras" and "psychographs" or substantial royalties for books—may explain the former, but wherefore the victims? The secret, we opine, lies in a defect of education. The young are taught to think, but not *how* to think. It is of minor import whether the conclusions in which thoughts terminate are or are not in accordance with fact. What is of vital importance is the character of the mental processes. It is wrong thinking rather than wrong thoughts that so often mars the individual, undermines society, and imperils the State. *Circumspice!* So long as the young growing child does not learn *how* to think, there will inevitably be an undue proportion of grown-ups whose pitiful logic consists in drawing false conclusions from unsound premises, and to whom error appears as truth provided it be shouted sufficiently loudly and frequently.

C. MARSH BEADNELL.

A Great American Agricultural Cyclopædia.

(1) *Cyclopedia of Farm Crops: A Popular Survey of Crops and Crop-making Methods in the United States and Canada.* Edited by L. H. Bailey. Pp. xvi+699+25 plates. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1922.) 25*s.* net.

(2) *Cyclopedia of Farm Animals.* Edited by L. H. Bailey. Pp. xvi+708+25 plates. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1922.) 25*s.* net.

DR. L. H. BAILEY has edited more agricultural books than any other man living, but he can never have excelled the two volumes that constitute this Cyclopædia. One volume deals with crops: the other with animals. Of agricultural crops there are in the United States between one and two hundred, quite apart of course from the innumerable plants coming within the province of the horticulturist. In these volumes a generous view is taken, and room is found for medicinal plants and plants yielding fibre, paper, oil, dyes, etc., which would not usually be included in an agricultural list. The animals are less

numerous, but even here the list is much larger than would have been expected, and is made to include pets, fish, game, and productive insects, as well as the usual poultry and live-stock. The volumes are the direct descendant of the well-known Cyclopædia of American Agriculture, which has run out of print and by reason of the cost will not be reprinted *in extenso*.

(1) The plan of the volume dealing with crops is to start with an account of the life processes of the plant, well written by W. J. V. Osterhout, followed by descriptions of the effects of stimulation by artificial light, weak poisons, and electricity; then to deal with insect and fungoid pests, and afterwards with plant breeding. The more technical part commences with accounts of the general principles of crop production and farm management, rotations, the growth of crops under cover, etc., and finally comes the long list of field crops, each of which is dealt with in detail.

More than a hundred experts have contributed to the volume and they have amassed a wealth of interesting material, much of which seems very strange to English readers. How many agriculturists in this country are familiar with the agricultural process of "singeing the cholla"? This operation is described in connexion with the cactus which constitutes a considerable part of the vegetation in the southern part of the range country, New Mexico and Arizona. Unfortunately the natural cacti are in the main spiny, and the attempts to introduce spineless forms useful to stock have not proved particularly successful. Nothing daunted, however, the American ranger has proved equal to the situation; by means of a gasoline blow-lamp the spines are singed off, with the result that the cacti become much relished by live-stock and are literally devoured, the prickly pears being eaten nearly to the ground, while only the trunks and woody branches of the chollas (*Opunta fulgida*) remain.

Turning to agriculture proper, the most important and most distinctive crop of the United States is maize, there always called "corn." It is described as of Mexican origin and related to Mexican grass teosinte (*Euchlæna Mexicana*). The annual value of the crop exceeds that of any other in the States, and is estimated at more than a billion dollars: the most important individual States are Illinois, Iowa, Nebraska, Missouri, Kansas, and Indiana; the least important are Montana and Wyoming. The yield varies from less than 10 bushels per acre in Florida to 35 or 36 bushels per acre in Connecticut, Massachusetts, Maine, and Pennsylvania. Its different varieties are, to a greater extent than those of any other crop, capable of adaptation to local conditions; some mature in seventy or eighty days, and are thus suited to the short seasons of the North; these attain a height of 3 ft. or 4 ft. only. Others found in the South have a growing season of six months, and may reach a height of 20 ft. or more. The crop fits well into rotation farming, and therefore is assured of a permanent place in agriculture.

Another highly important crop is wheat, the area of which increased greatly in the States during the period in which it was shrinking here. Wheat is, however, essentially a pioneer crop, and it tends to shift towards the newer countries. Thus, during the past fifty years the centre of wheat production in the United States has moved westwards more rapidly than has the centre of the population. In 1850 New York was one of the great wheat-growing States; now it produces only a little more than 1 per cent. of the United States crop. Later on, Southern Wisconsin and Northern Illinois became the chief wheat States; now Kansas and North Dakota take the lead. Plant breeders and seedsmen have been busily occupied with the crop, and an immense number of different varieties have been grown: so far back as 1895 the U.S. Department grew more than 1000 different sorts for several years, though a number were found to be identical, and only about 250 were of any value to American growers. Since then the varieties have increased considerably.

Unlike Great Britain, the United States has a large area of spring-sown wheat, and, moreover, much of its wheat is grown under drier conditions than prevail here. There are still sections of the semi-arid country where no rotation is adopted and where wheat simply alternates with summer fallow, though, as Dr. Lyttleton Lyon points out, this will probably before long be replaced by a rotation including perennial grass or leguminous crops left down for some years. Elsewhere in the corn belt much of the spring wheat supply alternates with maize, though the winter wheat is usually grown in a rotation—maize, maize, oats, wheat, clover. This is somewhat of the same type as British wheat growing, with the substitution of wheat or oats for the first maize crop and roots for the second. The harvesting, however, is carried out altogether differently, and we have in this country nothing approaching the "Header" or the "Combine" now in use in parts of the States.

As the book is written for American agriculturists there is no specific account of British crop production. There are, however, casual references, not all of which are accurate. Thus, it is stated that spurrey is cultivated by dairy farmers in Great Britain, which we believe is not the case.

(2) The volume on animals is equally rich in stores of interesting and valuable material. It is gratifying to a native of Great Britain to find how large a part is played by animals which originated here: horses,

sheep, cows, pigs as used on the best farms have been distributed from this country, which still fortunately retains its best studs. British readers will turn with much interest to the account of the bison, which, it is suggested, has agricultural possibilities. It is not in itself a particularly tractable animal; the young calves are ready to fight within a few minutes of birth; but it crosses with the domesticated cow to produce a hybrid known as the "cattalo," which is said to offer possibilities.

Altogether the volumes will be found of much value to the student of agriculture, and they reflect great credit alike on the editor, the contributors, and the publishers. E. J. RUSSELL.

History of Electrical Science.

Bibliographical History of Electricity and Magnetism, Chronologically Arranged. Compiled by Dr. P. F. Mottelay. Pp. xx+673. (London: C. Griffin and Co., Ltd., 1922.) 42*s.* net.

THE title of this book and its subtitle, "Researches into the Domain of the Early Sciences, especially from the Period of the Revival of Scholasticism, with Biographical and other Accounts of the most Distinguished Natural Philosophers throughout the Middle Ages," well describe the contents. Every scientific man is interested in the early days of science, and most of them know a few traditions about its history. It will be a boon to them to find out how far these traditions are justified by the facts, and this book of Dr. Mottelay's, whose death we had recently to deplore, will be of the greatest assistance to them. The volume gives very complete references to all the discoverers of the laws of electricity and magnetism and the writers on these subjects. The author starts from the dawn of authentic Chinese history (2637 B.C.) and ends with Christmas day 1821, when Faraday converted electrical into mechanical energy by causing a wire carrying a current to rotate in a magnetic field.

Many photographic reproductions are given of pages from ancient books and manuscripts. In particular the reproductions of pages from the "Epistola . . . de magnete" of Petrus Peregrinus (1269) taken from the Bodleian MS. and from an almost illegible MS. in the Bibliothèque Nationale at Paris are extremely interesting.

Roger Bacon, a contemporary of Peregrinus, describes him as a "thoroughly accomplished, perfect mathematician." He wrote the earliest-known treatise on experimental science and gave the first description of a pivoted compass. A full description is given of Dr. Gilbert's (1600) "De magnete . . .," in which reasons are given for supposing that the earth is a magnet. Sir Isaac Newton in a private letter (1716) seems to have partially anticipated Franklin's discovery that a lightning flash was electrical in origin. He writes: "I have been much amused by ye singular *φενομενα* resulting from bringing a needle into contact with a piece of amber or resin fricated on silke clothe. Ye flame putteth me in mind of sheet lightning on a small—how very small—scale." It is not generally known that the great French physicist and mathematician Poisson described the method of obtaining the horizontal value of the earth's magnetic field in absolute measure (1828). Sturgeon mentions that Snow Harris, who used strips of copper for his lightning conductors, carried the lightning conductor of a small man-of-war through the powder-magazine!

This volume deserves a place in every scientific library. To electrical engineers of all nationalities it makes a special appeal. A. R.

Organic Chemistry.

(1) *Grundlegende Operationen der Farbenchemie.* Von Prof. Dr. H. E. Fierz-David. Zweite verbesserte Auflage. Pp. xiv+266. (Berlin: J. Springer, 1922.) 300 marks; 12*s.*

(2) *Organic Chemistry.* By Prof. W. H. Perkin and Prof. F. S. Kipping. Entirely new edition. Part 1. Pp. xi+681+xx. (London and Edinburgh: W. and R. Chambers, Ltd.; Philadelphia: J. B. Lippincott Co., 1922.) 8*s.* 6*d.* net.

(3) *Trattato di chimica generale ed applicata all' Industria.* By Prof. E. Molinari. Vol. 2: Chimica organica. Parte seconda. Terza edizione riveduta ed amplicata. Pp. xv+625-1406. (Milano: Ulrico Hoepli, 1922.) 48 lire.

(1) THE first edition of Dr. H. E. Fierz-David's volume on the chemistry of dyeing has been translated into English, and is by now well known to English chemists connected with the manufacture of synthetic dyestuffs and to students of chemistry preparing for that branch of industry. It is a book which has supplied a distinct and ever-increasing demand.

The preface to the new German edition is interesting in so far as the author, who thought fit to suppress certain processes in the interest of the home industry, now finds that these methods with little modification are common to all countries manufacturing "intermediates," and that there is nothing which he has described which will affect the Swiss colour-makers.

(2) The text-book of organic chemistry by Perkin and Kipping is too well known in our universities and colleges to need more than a brief reference to the new edition. It contains some important additions, notably

chapter 42, in which an account is given of the use of catalysts in organic chemistry, the hardening of oils, Thiele's theory and the cracking of petroleum. An extension of the sugar group is given in chapter 39. No doubt in a future edition of the book these somewhat incongruously grouped subjects will be allotted their proper places.

Minor modifications and additions are the explanation of the reactions which occur in the preparation of formic acid and of allyl alcohol from glycerol and oxalic acid in accordance with Chattaway's work and Werner's method for the preparation of methylamine from formaldehyde. Some parts of the chapter on the terpenes have been modified, and several new synthetic products have found a place.

(3) Prof. Molinari's organic chemistry, which was translated into English by T. H. Pope, constitutes vol. 2 of his treatise on chemistry. Since its first appearance a second and third edition of the organic section have appeared, the last being so much enlarged as to necessitate a division into two parts, each of substantial dimensions. The first part has already appeared in its English dress, and no doubt the second part, the subject of the present notice, will soon follow. Although this treatise has already been reviewed in these columns (NATURE, May 12, 1921, p. 325), it may be again stated that the organic section is in many respects unique. As the title states, it deals with general chemistry and chemistry applied to industry. The industrial part is not merely a bare text-book outline of the process, such as the text-book compiler occasionally introduces from conscientious motives, but without either knowledge of or interest in the subject. The descriptions are such as might be found in a specialised treatise dealing with the processes and are illustrated by excellent diagrams and drawings of apparatus, often with cost of plant and appliances. Moreover, analytical methods and figures are given with numerous statistics of imports, exports, and prices.

Such a comprehensive combination of the theory and practice of chemistry is in itself illuminating, and one may turn over page after page and find a store of information, of which the non-technical chemist has probably never heard. It gives a clear picture, more impressive indeed than the splendid "Dictionary of Applied Chemistry," of the invasion of industry by science and the widespread extent of that invasion. It is a treatise upon which both author and publisher and also the translator may be congratulated, and one feels sure that the friendly appeal of the publisher attached to the volume by a slip of paper in which he "offre questo volume in omaggio con la preghiera di raccomandarlo agli amici e favorirne la diffusione" will find a favourable response. J. B. C.

Our Bookshelf.

The Old English Herbals. By Eleanour Sinclair Rohde. Pp. xii + 243. (London: Longmans, Green and Co., 1922.) 21*s.* net.

THE subject of herbals has always attracted students of botanical history. The beauty of their figures, the quaintness of their language, their appearance as the herald of the scientific development of botany, their appeal to the folklorist and designer, have all combined to create a demand for these books. Dealers have not been backward in reflecting the extent of this demand in the prices they have put upon them.

It may be doubted, however, whether the scientific student of the history of science will pay quite the same importance to these herbals as is attached to them by the collector. Undoubtedly the manuscript herbals and some of the earlier printed herbals represent a stage in the development of science. For the most part, however, their preparation has demanded little thought—except from the illustrator—and no general ideas. Some of the most picturesque of them are even behind the scientific development of the time in which they appeared.

Some years ago Mrs. Agnes Arber, in her admirably illustrated and arranged work on "Herbals," produced a scholarly general account of these books. Miss Rohde confines herself to those of English origin. The choice is, perhaps, unfortunate in one important respect since, in fact, few of the herbals which had any influence on the course of botany were produced in this country. On the other hand, her choice has provided an admirable opportunity for giving a picture of the attitude towards botanical studies in this country in the sixteenth and seventeenth centuries. The book, too, is packed with a good selection of the very quaintest quotations, by which the sternest critic will be at once charmed and disarmed. If they are not always relevant they are always entertaining. No reviewer will put down the volume without the feeling that whatever its faults he has been presented with a most readable and entertaining book, and after all, what are books for save to be read and to entertain? The would-be writer of the slashing article—if any of that iron breed yet survive—will find that Miss Rohde has smiled him into good humour long before he has turned the second cover. The illustrations, too, are excellent, the volume is remarkably cheap, and the bibliography useful.

Essentials for the Microscopical Determination of Rock-Forming Minerals and Rocks. By Dr. A. Johannsen. Pp. vi + 53. (Chicago: University of Chicago Press. London: Cambridge University Press, 1922.) 11*s.* net.

PROF. JOHANNSEN has deserved well of petrologists. The present publication by him comprises some half-a-dozen tables, explained and illustrated by notes and diagrams. The minerals are classed in the first place according as they are opaque or transparent, isotropic or uniaxial or biaxial, uncoloured or coloured, and pleochroic or non-pleochroic, and to each of these divisions is allotted a table. In the tables the aniso-

tropic minerals are arranged vertically in the order of their birefringence indicated in the central column; and laterally from the centre outwards, according to their refractive indexes shown at the top of the table. The range of the refractive index of each mineral is given by a horizontal line, somewhat in the same manner as in the "Petrographic Methods" of Dr. Holmes.

Comparatively little use is made of the optic axial angle, though even a rough estimate involving no elaborate procedure or calculations may be quite useful. Another observation which can be made without difficulty is whether the direction of maximum absorption coincides with the fast or the slow direction of vibration. The sections dealing with the felspars, pyroxenes and amphiboles are excellent, but the use of the term melatope (p. 32) for the point of emergence of an optic axis in interference figures should have been explained.

The concluding pages are devoted to the author's new quantitative classification of igneous rocks, which is based on the "mode," the actual minerals present, instead of on the "norm." Most petrologists in this country believe, however, that any quantitative system of classification is essentially misleading.

J. W. EVANS.

Annuaire pour l'an 1923 publié par le Bureau des Longitudes. Pp. viii+654+A118+B12+C16+D72. Supplément à l'Annuaire du Bureau des Longitudes pour l'an 1923: Distribution des pluies en France. 15 planches. (Paris: Gauthier-Villars et Cie, n.d.) 6.50 francs.

THIS very handy little volume is now widely known, and the issue for 1923 shows no falling off in its general utility; it contains all the usual calendar information, and has tables and descriptive matter dealing with all classes of heavenly bodies; there are also physical, mensurative, and geographical tables. The only point in these tables that seems to call for some criticism is the section relating to comets. The orbits given are in many cases by no means the latest or most accurate available; the latest return of Encke's referred to is that of 1914, though it has been seen since then, in 1918 and 1921. The date given for the perihelion passage of the comet Pons-Winnecke in 1921 is June 20, which is eight days too late; it is also curious that this comet is called simply Winnecke's, forgetting that it was first found by the French astronomer Pons, and that its periodicity was known long before Winnecke found it in 1858.

The special essay contained in this volume is by M. G. Bigourdan on the climate of France; it contains many tables and diagrams, and discusses the different types of climate belonging to different regions, and also the diurnal and annual variations in cloud, rain, etc. M. Bigourdan describes the system of weather forecasts by wireless, which are now distributed daily, and should be of great service to agriculturists.

There are obituary notices of Gabriel Lippmann and Jules Carpentier, both of whom died last year.

The small suggestion may be made that the leaves of the book should be cut, as is usually done in volumes of this character, where ease of reference is a desideratum.

A. C. D. C.

Common Stones: Unconventional Essays in Geology. By Prof. G. A. J. Cole. (Common Things Series.) Pp. 259. (London and New York: Andrew Melrose, Ltd., n.d.) 6*s.* net.

PROF. COLE'S twenty essays on common stones are written with a literary grace and charm which should give this book a firm place among British popular presentations of science. It should do to-day the service which Kingsley's "Town Geology" did for an earlier generation. The volume sketches the modern theories of rock formation, on which the author writes with the knowledge of an expert, while his references to the field occurrence of the rocks make the reader share with him the pleasure of many field days. The chapters which deal with sedimentary petrology are especially useful; one of the most attractive is that on soils, as might be expected from the head of a Geological Survey which has devoted especial attention to agricultural geology.

Advanced students would profit by reading these essays, for they quote much new information and many unfamiliar instances; the author, for example, lays stress on the origin of oolitic structures by chemical processes, and on the formation of corries by nivation instead of by glacial erosion; he rejects some conclusions based on the low ash content of anthracite; in emphasising the need for safeguarding our future coal supplies he remarks wittily that a century hence a chapter on coal would be out of place in his volume, as coal would then be regarded as a precious and not as a common material.

The humanistic feeling shown in this book by its high literary quality and its frequent reference to the early founders of geology would make its perusal of special benefit to science students in view of the growing specialisation in their preliminary education.

Kincardineshire. By the late George H. Kinnear. Pp. xi+122. (Cambridge: At the University Press, 1921.) Price 4*s.* 6*d.* net.

KINCARDINESHIRE, though one of the smaller of the Scottish counties, is a compendium of Scottish geographical types, for it includes typical areas of highlands, lowlands, and of the eastern coastal districts. Kincardine is interpreted as "the end of the high lands" and it is used for various localities in Scotland; the name is appropriate to this county, as it includes the eastern end of the Grampians. The chief lowland area is the plain known as "the Howe of the Mearns" which is the eastern end of the Vale of Strathmore. The coast is very variable in character, and unusually picturesque; part of it consists of soft beds which are undergoing rapid abrasion by the sea; elsewhere occurs an alternation of hard rocks which project in headlands such as that surmounted by Dunnottar Castle, and of soft bands which have been worn back into bays. The interest of the coastal scenery is enhanced by the numerous stacks and caves. The headlands act as groynes, and their protecting effect was shown in the case rendered classic by Lyell, who recorded the destruction of the village of Mathers on a single night in 1795 owing to the sea breaking through a ledge of limestone which had been weakened by quarrying. Fishing villages are numerous along

the coast, and one of them, Findon, has given its name to the "finnan haddock." The population is lowland and included the ancestors of Burns. The sections on the geology and meteorology of the country are well up-to-date; the author, for example, attributes the mild climate of Scotland to the south-west winds and not to the discredited Gulf Stream.

Zeitschrift für angewandte Geophysik. Unter ständiger Mitarbeit zahlreicher Fachgenossen. Herausgegeben von Dr. Richard Ambronn. Vol. i., Part I. Pp. 32. (Berlin: Gebrüder Borntraeger, 1922.) 20*s*.

WHILE the attention of geologists is justly turned to physical considerations, in view of our immense ignorance of the inner constitution of the earth, it may be questioned if it is wise at the present time to inaugurate a special journal for geophysics. The first part of the *Zeitschrift für angewandte Geophysik* is issued under the editorship of Dr. R. Ambronn, of Göttingen, by one of the most enterprising firms in Germany. Its thirty-two pages are priced at twenty English shillings, which puts it beyond the reach of scientific men who are also taxpayers in our islands. We cannot help feeling that the money would be better spent in supporting and, if necessary, enlarging the scope of one of the German geological journals that have already won a world-wide reputation.

Dr. Ambronn shows how the measurement of radio-activity, of variations in gravity from point to point, of the increment of temperature with depth, and of the propagation of earthquake waves, subjects that truly belong to the domain of geophysics, find their applications in the search for ore-bodies, basins of light minerals, such as rock-salt, and of petroleum. Abstracts are given of papers which deal with these or similar subjects; but they will surely fall under the watchful eye of the editor of the *Geologisches Zentralblatt*, to mention only one well-known journal. We compliment Dr. Ambronn on his energy, but not on his adding yet another care to our librarians, however casually his new periodical may appear.

G. A. J. C.

Essays on the Depopulation of Melanesia. Edited by Dr. W. H. R. Rivers. Pp. xx+116. (Cambridge: At the University Press, 1922.) 6*s*. net.

IT is difficult to lay too much stress on the practical value of this small collection of essays written by members of the Melanesian Mission and others. The fact that the volume is edited by the late Dr. W. H. R. Rivers is a guarantee both of accuracy and impartiality. Sir Wm. Macgregor and Mr. C. M. Woodford, who write from the point of view of the official, and Dr. Speiser of Basle, who writes as an anthropologist, fully bear out the contentions of the members of the Mission. The authors, without exception, agree that depopulation in Melanesia is to be attributed largely to the breaking up of custom which has followed contact with the white man. When the spiritual power of the chief has been discredited in the eye of the native by the white man, the temporal authority, which is based upon it, fails to preserve traditional law, order, and morality. Dr. Rivers, in a concluding essay, however, suggests that the most important factor is psychological. The native, he maintains, has lost all interest in life through the suppression of customs such as head-hunting, with which have disappeared a large number of closely related social activities. His suggestion that total suppression of such customs could be avoided by substitution of harmless elements is deserving of careful consideration.

Quaker Aspects of Truth. By Dr. E. V. Brown. Pp. 156. (London: The Swarthmore Press, Ltd., n.d.) 5*s*. net.

THE little book under notice consists of a series of lectures illustrating simply the Quaker attitude to various problems. In the chapter on biological foundations, the author attempts to show that the fundamental doctrines of Quakerism, *i.e.* the acknowledgment of no final authority, whether Church or Bible, except the Word of God in the heart, are more in accord with the teachings of biological science than the dogmas of any other religion. The point of view is interesting, although it is doubtful whether the teachings of science, as such, are usefully fitted on as justification for a body of religious beliefs.

The author develops his contention that the Quaker ideal is Christianity from which all accretions in the form of Hebrew, Greek, and Roman sources have been eliminated. He also discusses the Quaker attitude towards war.

The essays all set forth high moral ideals, for the value of which the moral life of the believer in them is the sole criterion.

Chemistry of To-day: The Mysteries of Chemistry lucidly explained in a Popular and Interesting Manner free from all Technicalities and Formulæ. By P. G. Bull. Pp. 311. (London: Seeley, Service and Co., Ltd., 1923.) 8*s*. 6*d*. net.

ACCORDING to the preface, this is not intended as a text-book, but as an attempt to give some account of modern chemistry to the general reader. It should fulfil this object: the style is bright and interesting, the matter appears to be accurate, and an extensive field is covered—very superficially for a text-book, but probably adequately for the intended reader. There is perhaps too great a tendency to "sensational" topics—the frontispiece representing a well-known man of science "bombarding" atoms half the size of himself with "nuclei of helium" as big as cricket balls, and producing a pyrotechnic display, is an example of what we mean by this criticism. There are good half-tone plates, but the line-drawings are poor.

The Psychology of Society. By Morris Ginsberg. Pp. xvi+174. (London: Methuen and Co., Ltd., 1921.) 5*s*. net.

IN short compass Mr. Morris Ginsberg discusses critically with admirable lucidity the psychological basis on which much recent treatment of social problems is founded. He has a keen eye for essentials, and a sense of perspective. He presents tersely and fairly the salient arguments of writers who count and pronounces clearly and courteously well-considered judgment. A little book but a good one.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Spectrum of Neutral Helium.

AT the end of his letter to NATURE of January 13, p. 46, Dr. Silberstein appends a note to the effect that he has been able to express the diffuse series HeD′ in the form

$$n = 109723\{1/2^2 + 1/10^2 - 1/9^2 - 1/m^2\}$$

with errors of 0·7Å for the second line, and of between 0·1Å and 0·35Å for the next ten. May I be allowed to offer the following remarks:—

(1) A formula determined on a definite hypothesis, as here, ought to reproduce the wave-lengths within observation errors or at least be able to account for deviations from them. According to the data given the deviations amount to between 100 and 200 times the possible errors (700 for the second). The usual empirical formula reproduces all the lines within these limits, except the first, the O − C errors being 0·000 for $m = 2$, 3, 4 and the largest for higher values of m being 0·02. The limit is definitely within ± 0·1 of 27175·68 I/Å, in other words, $N(1/2^2 + 1/10^2 - 1/9^2)$ must have this value. This, of course, is possible by an empiric choice of N, but it would probably upset even the rough agreement when this is used in the last term N/m^2.

(2) That the diffuse singlet series HeD′, and indeed also the diffuse doublet HeD″, can be represented roughly in the form $A - N/m^2$, is due to the fact that for this special series the denominator in the empirical formula, $m + 0{\cdot}996369 + 0{\cdot}002917/m$, is necessarily very close to a whole number, and its deviations therefrom produce comparatively small effects when m becomes large. A similar arrangement in the cases of S′, S″ or P″ would be found impossible.

(3) But the most fatal objection is that $N(1/2^2 + 1/10^2 - 1/9^2)$ must also be the first term of the p' sequence, which is at least numerically represented by $p'(m) = N/(m + 1{\cdot}014593 - 0{\cdot}004392/m)^2$. Here again the denominator is nearly an integer (though further from it than in $d'(m)$), and no doubt it could also be represented by N/m^2, with greater deviations than in the case of d', but the first term would then be $N/2^2$ and not $N(1/2^2 + 1/10^2 - 1/9^2)$.

It is perhaps a difference in temperament, but to me Dr. Silberstein's note appears rather to weaken than to give a "much stronger support" to his proposed theory. However, I am not here discussing his hypotheses, one objection to which I raised in a letter to NATURE on September 2 last (p. 309) which Dr. Silberstein has not dealt with.

W. M. HICKS.

January 15.

Some Experiments on Rate of Growth in a Polar Region (Spitsbergen) and in England.

IN a recent paper (Journal Mar. Biol. Assoc., vol. 12, 1920, p. 355) attention was directed by me to the lack of critical evidence bearing on the theories offered to explain (*a*) the abundance of life in polar regions, and (*b*) the occurrence of several generations of a species living side by side in polar waters. Murray and Loeb and others have suggested that an explanation of these phenomena may be found in a greatly retarded rate of growth which, it is *postulated*, must occur in the low temperatures prevailing in these regions. The present writer urges (*a*) that we know nothing about the rate of growth of organisms in polar regions, and (*b*) that the kind of metabolism of animals in polar regions—and in deep-sea situations—is not necessarily the same as that in temperate or tropical regions. A given organism may be regarded as a machine, but it is perhaps derogatory to the kind of machine one is dealing with to assume that other life-machines existing under totally different conditions are necessarily governed by identical applications of the same laws; for example, it does not necessarily follow that because the rate of metabolism in tropical or temperate animals falls off rapidly with decreasing temperatures approaching 0° C., that metabolism in polar animals is necessarily of the slow rate of temperate animals at polar sea-temperatures. No reason has yet been shown that adaptation of metabolism cannot occur; on the contrary, there is every reason to expect such adaptation.

The following experiments on the rate of growth in marine organisms at Spitsbergen—designed to obtain information on these problems—have given, however, mainly a negative result, but as in one case a positive result—yielding a much greater rate of growth than has ever been suspected—has been obtained, it is worth while recording the result now. It is hoped to write a fuller account later, giving details of the apparatus used, in the Journal of the Marine Biological Association.

In 1921 simple experiments on rate of growth were carried out in 7 fathoms of water close to Anser Island in Klass Billen Bay, Spitsbergen, by the biologists of the Oxford Spitsbergen Expedition, and mainly under the direction of Mr. Julian Huxley and Mr. A. M. Carr Saunders. The present writer had hoped to carry out the experiments under personal supervision, with the promised help of Dr. Hoel of the Norwegian Fishery Board, but circumstances nullified these arrangements.

Two pieces of apparatus were used—a galvanised iron-wire network cage of ⅝-inch mesh and 5 feet by 4 feet by 9 inches was tarred and moored to the bottom of the sea after putting a large number of dried oyster shells inside it; and a floating tarred wooden raft with strings of shells attached was anchored in the sea near the cage. The apparatus was put in the sea on June 27, 1921; the raft and shells were inspected by Mr. Huxley on July 16, and—owing to the illness of Mr. Carr Saunders—finally hauled by Mr. R. W. Segnit, geologist, and Capt. Johannsen on August 24, 1921.

On July 16 Mr. Huxley found practically no growth on the raft nor on the shells on the raft, but the cage was not hauled. On hauling the cage on August 24 the sea-urchins shown in Fig. 1 were found *inside* the cage. The door of the cage, which only covered the central portion of one long face of the cage, was found to be closed and *laced* as had been previously arranged on putting the cage in the sea. The astonishing sight of the relatively large sea-urchins inside the cage attracted attention at once, and a fruitless examination of the cage was made for any means of access greater than the mesh of the cage. The conclusion was therefore drawn that the urchins must have entered the cage while small, *i.e.* of a diameter upwards to about 1·6 cm., and grown to the size observed, *i.e.* upwards to about 2·9 cm. in diameter—excluding spines—within 58 days.

This result was regarded as very important, and a confirmatory experiment tried again at the same spot in 1922, under the direction and by the kindness of Mr. J. Mathieson, of the Scottish Spitsbergen Syndicate scientific staff. When Capt. Johannsen

hauled the cage in 1922, however, no urchins were found this time in the case, and no growth observed on the cage or shells.

In 1921 Mr. Mathieson took a few sea-temperature observations which confirm the general indication that no higher sea-temperatures than 4° C. prevailed during the course and in the locality of the experiment.

The almost complete absence of growth on July 16, 1921, on Mr. Huxley's inspection is not significant, as I have found that failure to infect shells obviously with growth may occur in a similar period at Plymouth. The absence of growth, other than the sea-urchins, on August 24, 1921, may or may not be due to slow rate of growth and cannot be discussed adequately here, but at Plymouth the writer has found that in a period of 3 to 6 weeks in summer experimental shells may become covered with extensive growths of marine organisms, some of which may indeed have already attained sexual maturity. There is no doubt that the Spitsbergen sea-urchins were browsing on the oyster shells in the cage. An analogous result has also been obtained in cage experiments at Whitstable, where more than twenty relatively large starfishes (*A. rubens*), of a diameter of upwards to 16·8 cm. as measured from tip to tip of alternate arms, have been found on different occasions inside cages exactly similar to that used at Spitsbergen. In these cases there can be no doubt that the starfishes were attracted to the cage by the dead or dying animals inside the cage.

The rate of growth of sea-urchins in temperate waters under natural conditions is not known with accuracy, but Elmhirst estimates (see NATURE, November 18, 1922)—and I agree—that *E. esculentus* (which is a large species) may grow to a diameter of 4 cm. in one year. In a similar cage experiment on oysters at Whitstable a sea-urchin, *E. miliaris* (a relatively small species which does not attain more than about one-fourth the size of *E. esculentus*), was obtained on March 11, 1921, of a diameter of 2·7 cm. (excluding spines) after the cage had been in the sea 65 days, giving a minimum growth in the period of 1 cm. in diameter. On another occasion specimens of *E. miliaris*, of a diameter of upwards to 3 cm., were taken from the bottom of a floating coal-hulk, the *London City*, moored at Brixham, on August 1, 1911, after that vessel had been in the water after cleaning since April 1910. These sea-urchins were therefore rather more than one year old. The sea-urchins from the Spitsbergen cage experiment have not yet been definitely identified, but they probably grow to about the same size as *E. miliaris*.

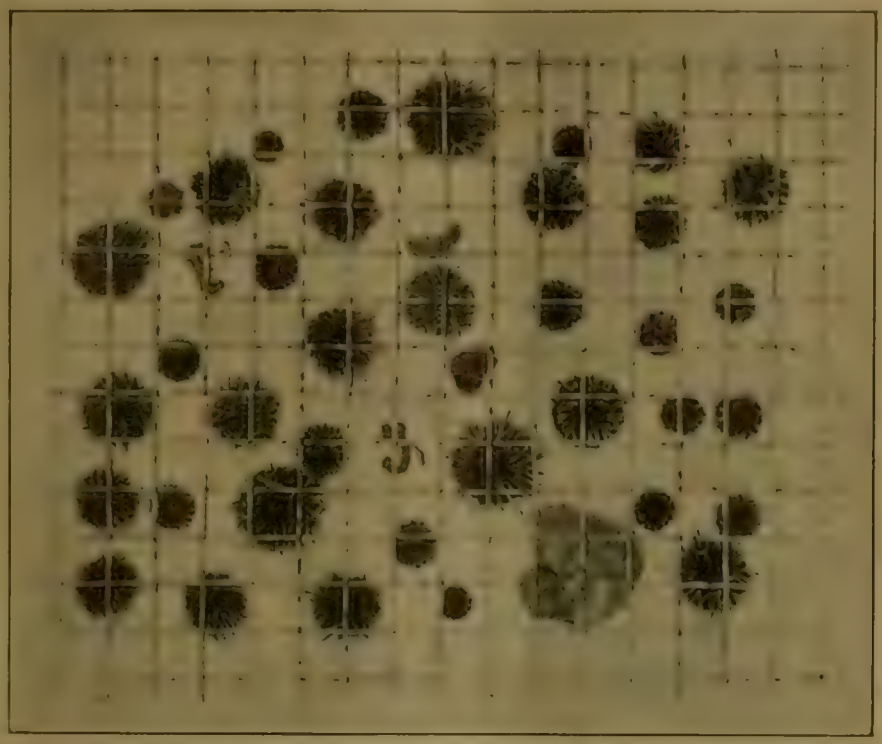

FIG. 1.—Photo[1] of sea-urchins from the cage experiment at Spitsbergen, 1921, seen through a grating of the same mesh as the cage. (¼ natural size.)

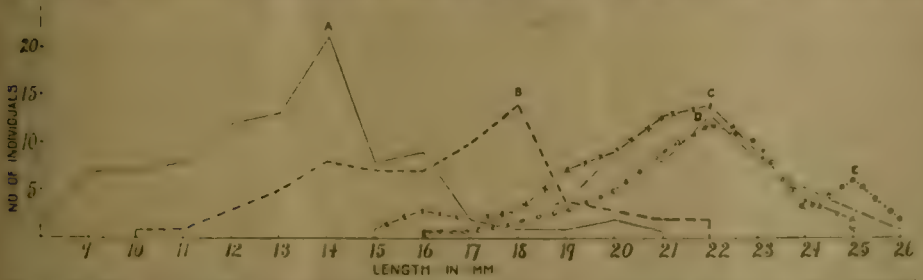

FIG. 2.—Showing[1] rate of growth of a fixed population of marked cockles (*Cardium edule*) kept in a box with perforated sides and top fixed to the bed of the River Yealm, near Plymouth. The box was visited at intervals of one month, and the cockles measured.

A, size of cockles, August 16, 1919; B, September 12, 1919; C, October 11, 1919; D, November 10, 1919; E, December 10, 1919.

Note the practical cessation of growth after about October 11.

Other marine animals—for example, cockles—grow shell very rapidly in English waters in the warm months of the year, and may add from 4 to 6 mm. in length to their shell per month for 6 or 7 months. (See Fig. 2, which shows some unpublished results of experiments in 1919–20 on growth in a fixed population of marked cockles kept in a perforated box fixed to the bed of the River Yealm, near Plymouth.)

Thus the growth of the Spitsbergen sea-urchins compares favourably in rate with that of calcareous marine animals in England, and indicates a rate of growth in marine animals generally in polar regions

[1] The writer is indebted to Mr. A. J. Smith for the photo (Fig. 1), and to Mr. E. Ford for the lettering in Fig. 2.

not previously anticipated; but further experiments are required to confirm the result obtained before drawing the important conclusions it appears to warrant.

It is hoped to repeat this experiment and others at Spitsbergen in the future; but it is desirable that other workers more favourably situated should also carry out similar experiments extending over a longer period.

The actual outlay of expenses for the experiment in 1921 was borne by the Marine Biological Association, and in 1922 by a Government Grant from the Royal Society, but in both years essential help was provided by the Scottish Spitsbergen Syndicate and its scientific leader, Mr. J. Mathieson.

Separation of Mercury into Isotopes in a Steel Apparatus.

By 305 hours of repeated fractional vaporisation from a steel trough in a vacuum at low pressures we have obtained a difference of 0·1 unit in the atomic weight of mercury without other cooling than that given by ice. The trough holds 190 c.c. of mercury, but another larger apparatus has been constructed in which the capacity is 10 kilos. In this the mercury

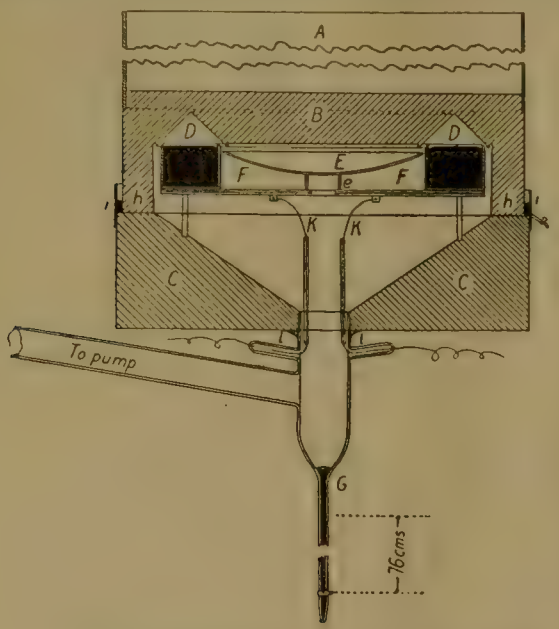

FIG. 1.—Steel apparatus for the separation of mercury into isotopes by vaporisation. *A*, Cylinder for ice; *B*, circular condensing roof, made of steel; *CC*, drain for the light fraction, made of steel; *DD*, annular steel trough holding 190 c.c. of mercury; *E*, watch glass with hole in centre, supported on a short glass tube *e*; *FF*, heating element made of calorised wire and supported on glass rods; *G*, collecting tube made of glass; *hh*, ground joint; *ii*, mercury seal; *KK*, platinum wires; *H*, ground joint and sealing wax.

is heated by an insulated wire which lies in the bottom of the trough, the insulation being obtained by a coating of magnesium oxide, which is covered with a steel sheath. This wire is produced by the General Electric Company.

The details of the apparatus are exhibited in Fig. 1. By means of the tube *G* the sample may be divided into as many fractions as is desired. In the newer form of apparatus the wires used as leads to the heating coil pass through insulators in the bottom steel plate, and not through the upper part of the tube *G*. The principle of the apparatus is that the lighter molecules, which vaporise more rapidly, strike the slanting roof above *D*, and collect in drops. These drops do not fall back into the trough of mercury, but roll down the slanting ceiling until they reach its edge, when they drop into the inverted cone in the lower steel plate, and then into the glass tube *G*, which has a capillary of 800 mm. length at the lower end.

The progress of the separation was followed by the use of Fig. 2, due to Mulliken and Harkins, and it was

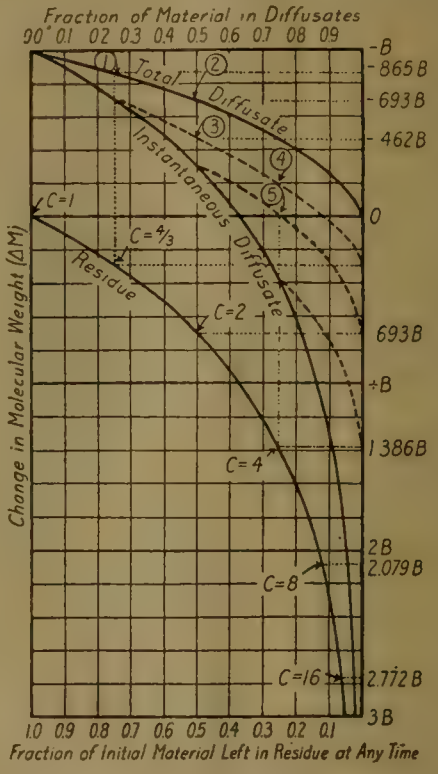

FIG. 2.—Generalised diagram showing atomic or molecular weight of fractions obtained during a 100 per cent. efficient diffusion or irreversible evaporation of a mixture of isotopes.

found that the efficiency of the process is quite constant and equal to about eighty per cent. It may be stated that Dr. Mulliken is also separating the isotopes of mercury in this laboratory, using the method of evaporative diffusion, which has an extremely high efficiency. His results will be reported separately. Our own work will be described more fully later, in the Journal of the American Chemical Society.

The Rule of Priority in Nomenclature.

As a teacher of palæontology and keeper of palæontological collections, I may perhaps be permitted to bring forward for discussion some trenchant points which seem to call for immediate action.

The rule of priority was originally intended to be a help in clearing away obscurity in nomenclature, but it is now seen that the strict observance of this rule is having a reverse effect.

The notice by E. H.-A. and A. E. of Cushman's "Shallow-water Foraminifera of the Tortugas Region" (NATURE, June 3, p. 708) is timely, for there they point out, "It appears to be undesirable to complicate synonymies by the revival of early names." They also deprecate the resuscitation of "Discorbis" for "Discorbina," and "Quinqueloculina" and "Triloculina" for "Miliolina." These minor differences in the plans of growth are not generic, for we find them, as often as not, slipping past the boundaries we have set for them.

Names of genera, especially those of the mollusca, are out-of-date in textbooks almost before they reach the hands of our students. Thus Pleurotoma of Lamarck was changed, after many years of usage, to Turris of Bolten, through the unfortunate discovery of a catalogue in which genera were denoted by a known species, *Turris babylonica*, which happens to be first on the list. As a case in point, the student gets familiar with Turris, but in a few months the teacher has to inform him that Turris is not only extremely restricted but unrepresented in Australia, and the genus has been split up, not into subgenera, but into many new genera. Museum labels to the number of several hundreds have to be rewritten, and almost before the ink is dry another change may be made.

The rule of priority is a good one within bounds, but should there not be a retrospective limit placed on many groups, dating say from the time when they were first written upon with authority? This limiting date might well be settled by a conference of workers in those particular groups. In some instances this has been done, and flagrant offences against reason have been prevented. Thus, in 1916 a motion for the suspension of the rule in regard to the genera Holothuria and Physalia was passed by an American conference. In one case "Holothuria" was the name given in 1758 to the "Portuguese Man-of-War," and later, in its familiar sense, to the Bêche-de-Mer, by Bruguière in 1791. According to the rule, "Holothuria" or "Bêche-de-Mer" being invalid was to be superseded by "Physalia," the name accepted previously for the "Portuguese Man-of-War." "Holothuria" would have become "Boadschia" of Jaeger, 1833, and "Physalia" would have become "Holothuria"!

Even the indispensable and invaluable "Index Animalium" of Chas. D. Sherborn will not entirely remove our troubles, for doubts will arise as to an author's meaning on account of bad figures and descriptions. It is, therefore, of paramount importance that a consensus of opinion be obtained for each group as to specific limitations and interpretations of authors' names, and thus prevent those feelings of despair which overtake the specialist, and more especially the general worker, at the present time.

F. CHAPMAN.
National Museum, Melbourne.

Selective Interruption of Molecular Oscillation.

In NATURE of July 22, 1922, vol. 110, p. 112, correspondence occurred regarding the possibility of selectively interrupting haphazard molecular oscillation by means of special apparatus, narrower in certain specific directions than the mean free path of the gas in which it was immersed. In view of the fact that such methods have now been independently put forward by Mr. H. H. Platt in America (U.S.A. Patent, 1,414,895), the following aspect of the problem may be of interest, particularly since the possibility would appear to be rendered very much more clear by so regarding it. Fig. 1 represents a portion of a cone longer than that previously considered, its diameter, however, still being considerably less than the mean free path of the gas concerned, so that molecules of the latter may frequently cross from side to side without intermolecular interruption.

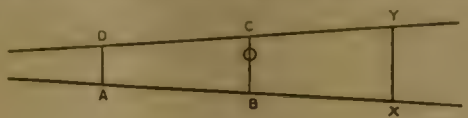

FIG. 1.

Let O be any little circle (or sphere if three dimensions are being considered) in this cone, and consider those molecules proceeding from collision, necessarily with equal probability of motion in all directions, outwards from the circle. If BC be drawn through the centre of O, parallel to the top and base of the cone, and if AD and XY be drawn equidistant from BC, then, provided regular reflection be presumed to occur as an average effect (compare *Phil. Mag.*, 1922, 43, 1954), it will readily be seen that of the molecules issuing from collision in circle O in any representative period of time, the ratio of the number of those crossing XY to the number of those crossing AD, however far (within free path distances) from BC these lines may be situated, will always be very considerably greater than the ratio of the length XY to AD (*Phil. Mag., loc. cit.* p. 1052).

If the gas is assumed to be initially of the same concentration throughout, and two dimensions only are being considered, then the number of molecules crossing these lines in any representative period of time will either be proportional to their lengths, or a change of concentration must occur. It has been shown that of the molecules proceeding from collision in circle O, an undue proportion will cross XY as compared with AD, and this is true (1) for all relative positions of AD and XY within free path distances from O, (2) for any and every position of O in the cone.

It follows, therefore, that molecules starting, with equal probability of motion in all directions, from collisions in the cone, will create a "condensation" or a disturbance of concentration towards the wider portion of the cone. The same effect may obviously be proved fully for three dimensions in a similar manner, and is really identical with that dealt with in the paper to which reference has been made, since

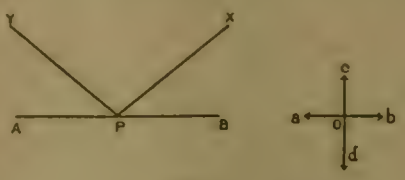

FIG. 2.

the whole cone is merely an extension of the one there described, sections ABCD and CDXY both being identical with the figure ABCD of the original paper.

Subsequent intermolecular collision in the cone cannot destroy the excessive downward bias so created, since this will merely be transferred to the other molecules concerned.

Fortuitous rebound from the walls, instead of regular "reflection," may be shown to lead to the same effect. If the wall AB be presumed to be ideally smooth, then a molecule approaching along path XP (Fig. 2) will be "reflected" along PY, receiving an impulse from the wall in the direction *oc*, the wall itself receiving the equal and opposite impulse in the direction *od*. If the wall be irregular, or owing to

thermal oscillation, or adsorption, or many other causes, it may in addition exert an impulse on the molecule in the direction *ob*, receiving the equal and opposite impulse along *oa*, or it may exert an impulse along *oa*, receiving one along *ob*. Should the former lateral effect predominate, the directing effect of the cone will be *increased*; should the latter predominate the effect will be reduced, but there is no reason to suppose that, in any representative period of time, either will predominate over the other.

ARTHUR FAIRBOURNE.

King's College, University of London,
Strand, W.C.2.,
January 1.

Sir Isaac Bayley Balfour.

ALL botanists and lovers of flowers will mourn the death of the Edinburgh professor, who served science and horticulture as few men have ever done. The occasion seems opportune to relate an incident comparatively unimportant in itself but in a manner typical. Many years ago a beautiful Primula, called by Greene *P. rusbyi*, was discovered in the Mogollon Mountains of New Mexico. Later, in the Sandia Mountains of the same State, one of my students found an apparently distinct species, which I named *P. ellisiæ*. These primroses occupied distinct and isolated mountain ranges, but were so similar, at least in the herbarium, that a German writer pronounced them identical. No one, so far as could be learned, had seen more than one of them alive, and it was the living plants we needed to settle the matter. I was able to procure seeds of *P. ellisiæ* for Prof. Bayley Balfour, and in 1921, when my wife and I visited him in Edinburgh, he not only had *ellisiæ* in full flower, but also *rusbyi*, the seeds of which he had secured from some other collector. It was a dramatic moment when the Professor held the two pots, one in each hand, and pointed out that the plants were quite distinct. Thus, in Edinburgh, we learned a lesson in New Mexico botany, which we had never been able to learn when resident for years in that region. No doubt others could relate parallel experiences.

Age and Area in Natural Selection.

THE account in NATURE (December 2, vol. 110, p. 751) of the discussion at Hull on "The Present Position of Darwinism" has interested me greatly. Of course I realise that such an account must be summary and omit much that is said, but I am struck by the fact that apparently none of the speakers mentioned what seem to me two fundamental and even fatal objections to the Age and Area hypothesis as a subject for the theory of Natural Selection.

In the first place, the fact that "genus" is a very inexact term, largely dependent on the "personal equation," seems to be completely overlooked. Some of us tend to large genera, some to small. In his article in the *Nineteenth Century*, Dr. Willis refers to a genus of more than 1500 species. In my opinion, to call such a group a genus is positively grotesque; it includes probably scores of what I would call genera. I can juggle the genera of echinoderms (my own special group) so as to lend apparent support to the Age and Area hypothesis, or I can re-define them so as to contradict it strongly, and in either case I can quote high authorities or give excellent reasons for my course.

In the second place, the Age and Area hypothesis really explains nothing. It merely restates in a more or less tabular way what every taxonomist, who has given any attention to distribution, knows is often the case. I say "often" because, as some of those who took part in the discussion at Hull pointed out, there are many cases of distribution which do not fall in with this tabulated arrangement. No *causal* connexion between age and area is brought out in the proposed hypothesis. The only causal factors suggested are time and an inherent tendency to diversification, and surely both of these are given abundant play in the theory of Natural Selection.

I note with interest, perhaps I might say amusement, the statement by Mr. Cunningham that Natural Selection is "as extinct as the dodo." It may be in the land of its birth, but it is still very much in evidence in America. Nearly every systematic zoologist whom I know personally believes in it as a factor in evolution, though the importance attributed to it may vary greatly. Prof. E. G. Conklin of Princeton, certainly one of our foremost zoological thinkers, has just completed a course of Lowell Institute lectures in Boston on "The Revolt against Darwinism," in which he has most clearly and emphatically stated his strong conviction, not only that such revolt is unjustifiable, but that Natural Selection is the most important theory that has yet been proposed for helping us to understand adaptation. It surely seems a little rash to call Natural Selection, or anything else, "extinct" because it has disappeared from one's own horizon. Horizons contract with increasing near-sightedness.

The Cause of Anticyclones.

MAY I be allowed to suggest that the region of an anticyclone finds its most likely interpretation as an area hemmed in by cyclone systems. I agree with Mr. Dines (NATURE, December 23, vol. 110, p. 845) that it is the mass of air over the area that is important. It is a matter of personal observation that, as Mr. Dines says, "the steady and persistently high barometric pressure that has prevailed over southern England during most of the autumn" has been associated with the overlapping high overhead *here* of the margins of cyclone systems that were simultaneously from west to eastwards on our north and on our south respectively. The phenomenon of contrary currents at *high* elevation is an inseparable feature, in my experience, of anticyclonic conditions.

May it not be a conditional factor of these anticyclonic high pressure areas (?) the "mass" of air being piled to excess and held *in situ* by the conflicting winds of over-reaching cyclone lips. The play of antagonistic forces of movement and of their accompanying contrasts of humidity and temperature may be answerable for all other anomalies of anticyclone areas. What are wanted are observations of winds of *highest* elevation, which are only to be obtained by the method of employing a projected telescopic image of the sun, which renders visible and legible the "wind-billows" of individual strata of movement.

The Name of the Pond Snail.

IN NATURE for January 13, p. 49, two writers of authority call this snail *Limnæa peregra*. The word "peregra" is not Latin—a fact which at one time had penetrated to the consciousness of most conchologists and malacologists but appears to have been again forgotten.

F. A. B.

Medical Education.

I REGRET that I have not the time to do justice to Sir Archdall Reid's last letter, which is supposed to deal with the above subject (NATURE, January 13, p. 50). It is, as I expected, really an attempt to open up another discussion on evolution. Now since Sir Archdall confesses to having already spent eighteen months vainly trying to find out what biologists mean, it seems inadvisable to begin again; for his letter indicates a very imperfect acquaintance with biologists and their work.

To my mind it is an amazing suggestion that zoologists and botanists are incapable of teaching evolution, and it is illuminating indeed to find that men are to come after them "who have observed, with a minuteness and accuracy impossible to workers among plants and animals." I shall be glad to meet the gentlemen when they arrive. Meanwhile, until these Supermen appear, it is highly desirable that first-year medicals, raw youths from school, should make their first acquaintance with the animal world through less expensive material than human bodies, and should approach a great profession with, what practice and theory have shown to be, the best introduction.

An Overlooked Feature in Four-legged Tadpoles of *Rana temporaria*.

ALL accounts of the metamorphosis of the common frog leave it to be tacitly inferred that when the front legs make their way through the operculum branchial respiration ceases, and that thenceforth breathing is effected by the lungs, skin, and mucous membrane of the mouth. It appears to have been entirely overlooked that from the time of the acquisition of free front legs until the tail is completely absorbed, and the little anurous frog leaves the water, branchial respiration continues, water being drawn through the nostrils into the mouth, and *discharged from the opercular chamber through a pair of crescentic apertures, one on each side immediately anterior to the base of the front leg.*

FIG. 1.—Ventral view of four-legged tadpole of *Rana temporaria* when absorption of tail is nearly completed. The arrows mark the exits of the water from the opercular chamber.

In July 1922 I was watching some tadpoles that had just acquired their front legs, and was keeping them in a shallow dish of pond water in which was a certain amount of suspended, finely divided solid matter. I observed that the tadpoles did not come to the surface of the water to breathe, but continued sitting at the bottom; and that the respiratory movements of the sides of the head were still proceeding in regular rhythm, but now were confined to the region posterior to the gape of the mouth, whereas prior to the appearance of the front legs the movements extended up to the extreme anterior end. Closer attention enabled me to detect minute solid particles occasionally entering the nostrils, and two fairly steady currents of water issuing from the posterior end of the head, one in front of the left and the other in front of the right leg.

On killing a few specimens I found a crescentic, slightly thickened lip bounding the anterior margin of each of these opercular openings, and was able to lift the flaps and pass bristles in at each, and out through the mouth, and conversely. This condition persisted until the absorption of the tail was completed.

Fearing that I might have encountered an abnormal family of tadpoles—they were rather unusually late in the season—I examined preserved specimens of which I have scores, collected years ago, in my laboratory for teaching purposes, and found exactly the same state of affairs in every one at this stage of development.

To make assurance doubly sure I had vertical longitudinal series of sections cut through four specimens; and these fully confirm the naked-eye observations.

I have little doubt that others have noticed the thickened crescentic lips of the two opercular apertures; for in a figure published by Milnes Marshall, and in another by Howes ("Atlas of Practical Elementary Zoology," 1902 ed., Pl. ix. Fig. xiv.) it is indicated. Probably it has hitherto been mistaken for a line of fusion between the body wall and the remnant of the operculum left after the front legs have penetrated it.

Smell and Specific Gravity.

IN the course of some other experiments which are being undertaken in the Psychology Department of the University of Edinburgh, a number of subjects were requested to arrange in serial order, according to smell, phials containing oil of cedar (C), origanum (O), sandalwood (S), and terebene (T). Twenty-two experiments were made in all, and tend to confirm the observations made by Haycraft, Cohn, Zwaardemaker, Heyninx, and others, with regard to odour and chemical constitution.

The serial arrangement was made, not according to the affect (pleasantness or unpleasantness) nor to the intensity, but according to "pitch," or "heaviness and lightness," "dulness and sharpness" of the sensation. The number of votes cast for the position of each substance in the series was as follows:—

	1	2	3	4
S	16	4	1	1
C	4	11	4	3
O	2	6	10	4
T	...	1	7	14

A serial arrangement according to specific gravity is thus represented by the voting: sp. g. S = 0·974-0·980, C = 0·939-0·96, O = 0·890-0·90, and T = 0·862-0·868. In nine out of twenty-two experiments the series was arranged without any error. The number of cases in which three of the osmyls were placed correctly was as follows: SCO 10, COT 9, SCT 14, SOT 15. SC and OT were correctly placed relatively to each other in 17 instances, CO in 14, SO and CT 19, and ST (the two extremes) in 21 out of the 22 experiments.

The serial arrangement as recorded above is therefore by no means entirely due to chance, and the number of errors made diminishes the greater the difference between the specific gravities of the substances employed. As the above substances of the terpene group are not compounds but complex mixtures, moreover, as the subjects without any further explanation were only instructed to smell and arrange them in a series, the results are sufficiently striking.

Greek Geometry, with Special Reference to Infinitesimals.[1]

By Sir T. L. HEATH, K.C.B., K.C.V.O., F.R.S.

GREEK geometry passed through several stages from its inception to its highest development in the hands of Archimedes and Apollonius of Perga. The geometry which Thales brought from Egypt early in the sixth century B.C. was little more than a few more or less accurate rules for the mensuration of simple figures; it was the Greeks who first conceived the idea of making geometry a science in and for itself. With Pythagoras and the Pythagoreans, who represent the next stage after Thales, geometry became a subject of liberal education. Apart from special discoveries such as those of the theorem of the square on the hypotenuse, the equality of the three angles of any triangle to two right angles, the construction of the five cosmic figures (the five regular solids), and the incommensurability of the diagonal of a square with its side, the Pythagoreans invented two methods which remained fundamental in Greek geometry, that of proportions (though in a numerical sense only) and that known as application of areas, which is the geometrical equivalent of the solution of a quadratic equation.

By about the middle of the fifth century the Pythagoreans had systematised the portion of the Elements corresponding to Euclid Books I., II., IV., VI., and probably III.

In the second half of the fifth century, concurrently with the further evolution of the Elements, the Greeks attacked three problems in higher geometry, the squaring of the circle, the trisection of any angle, and the duplication of the cube. Hippias of Elis first trisected any angle by means of his curve, the *quadratrix*, afterwards used to square the circle. Hippocrates of Chios, who also wrote the first book of Elements and a treatise on the squaring of certain lunes, reduced the problem of duplicating the cube to that of finding two mean proportionals in continued proportion between two straight lines, the first solution of which was by Archytas, who used a wonderful construction in three dimensions. Democritus, among many other mathematical works, wrote on irrationals; he was also on the track of infinitesimals, and was the first to state the volume of any pyramid and of a cone.

The fourth century saw the body of the Elements completed. Eudoxus discovered the great theory of proportion set forth in Euclid Book V. and the "method of exhaustion" for measuring curvilinear areas and solids. Theætetus contributed to the content of Book X. (on irrationals) and Book XIII. (on the five regular solids). This brings us to Euclid (*fl.* about 300 B.C.).

To the third century B.C. belong Aristarchus of Samos, who anticipated Copernicus; and Archimedes, who, with Apollonius following after twenty years or so, concludes the golden age of Greek geometry.

To come to the history of infinitesimals. The Pythagoreans discovered the incommensurable and maintained the divisibility of mathematical magnitudes *ad infinitum*. The difficulties to which the latter doctrine gave rise were brought out with incomparable force by Zeno in his famous Paradoxes and in other like arguments. Zeno's Dilemmas profoundly affected the lines on which mathematical investigations developed. Antiphon the Sophist, in connexion with attempts to square the circle, declared that by inscribing successive regular polygons in a circle, beginning with a triangle or square and continually doubling the number of sides, we shall ultimately arrive at a polygon the perimeter of which will coincide with that of the circle. Warned by Zeno's strictures, mathematicians denied this and substituted the statement that by following the procedure we can draw an inscribed polygon differing in area from the circle by as little as we please. Similarly they would never speak of the infinitely great or infinitely small; they limited themselves to postulating that by continued division of a magnitude we shall ultimately arrive at a magnitude smaller than any assignable magnitude of the same kind, and that by continual multiplication of any magnitude however small we can obtain a magnitude exceeding any assignable magnitude of the same kind however great. On this safe basis Eudoxus founded the whole of his theory of proportion and the method of exhaustion.

It has been remarked that the method of exhaustion, though a conclusive method of proof, requires previous knowledge of the result to be proved, and is of no use for discovering new results. This is scarcely true because, before the proof by *reductio ad absurdum* is applied, the area or volume has to be *exhausted*, and this process often indicates the result. The process means a summation of a series of terms; and there are different classes of cases according to the nature of the series to be summed. In one case (Archimedes' quadrature of a parabolic segment) the summation is that of the geometrical progression $1+\frac{1}{4}+(\frac{1}{4})^2+\ldots$. Archimedes sums this, nominally, to n terms only. He says nothing about taking the limit when n is increased indefinitely, but merely declares that the area of the segment, which is actually $A\{1+\frac{1}{4}+(\frac{1}{4})^2+\ldots$ *ad inf.*$\}$, is $\frac{4}{3}$ A, where A is the area of a certain triangle. It seems plain, nevertheless, that Archimedes found his result by mentally taking the limit. Other series summed by him are arithmetical progressions and the series of the squares of the first n natural numbers. In these cases Archimedes sums two series representing respectively figures circumscribed and inscribed to the figure to be measured, and then states a certain intermediate quantity to be the actual area or content required. Here again Archimedes, though he does not say so, states what is in fact the common limit of the two sums when the number of terms in the series is indefinitely increased, and a factor common to all the terms is at the same time indefinitely diminished. The result is actually equivalent to integration. There are some six cases of the kind depending on the integrations $\int x dx$, $\int x^2 dx$, $\int (ax+x^2)dx$ and $\int \sin\theta d\theta$ taken between proper limits respectively.

The reasons why the Greeks were so limited in the number of integrations which they could directly effect were that they had no algebraical notation and

[1] Abridged from the presidential address to the Mathematical Association, January 2.

had not discovered the modern developments of certain functions as series; nor had they discovered that differentiation and integration are the inverse of one another. There is little trace in Greek geometry of considerations corresponding to the differential calculus; the only case that seems certain is that of the subtangent property of a spiral which must have been obtained by the consideration of the instantaneous direction of motion, at any point on the curve, of the point describing it. If, as is probable, Apollonius, in his treatise on the *cochlias* or cylindrical helix, dealt with tangents to the curve, he would no doubt determine the direction of the tangent at any point in the same way.

But the Greeks were by no means limited to what they could obtain by direct integration. They were very ingenious in reducing an integration which they could not perform directly to another the result of which was already known. This must have been the method by means of which Dionysodorus found the content of an anchor-ring or tore and Pappus obtained his theorem which anticipated what is known as Guldin's theorem. In the matter of the anchor-ring the Greeks also anticipated Kepler's idea that the content is the same as if the ring be conceived to be *straightened out* and so to become a cylinder. The Method of Archimedes is mostly devoted to the reduction of one integration to another the result of which is known, but is remarkable also as showing how he obtained certain results otherwise proved in his main treatises. The method was a mechanical one of measuring elements of one figure against elements of another, the elements being expressed as parallel straight lines in the case of areas and parallel plane sections in the case of solids. This point of view anticipated Cavalieri. The elements are really infinitesimals, indefinitely narrow strips and indefinitely thin laminæ respectively, though Archimedes does not say so. But Archimedes disarms any criticism that could charge him with using infinitesimals for proving propositions by carefully explaining that the mechanical procedure does not constitute a proof and is only useful as *indicating* the results, which must then, before they are definitely accepted, be proved by geometrical methods, that is, by the method of exhaustion.

The Disappearing Gap in the Spectrum.[1]

By Prof. O. W. RICHARDSON, F.R.S.

II.

TURNING to Fig. 1, B, which is repeated here for convenience of reference, this shows the various outposts where from time to time spectral lines have been located. It will be seen that there is still a considerable gap between 16·35, the limit obtained with the vacuum grating at the L series of aluminium, and 17·39, the limit with the crystal spectrometer at the L series of zinc. Between these limits no spectral lines are known, but there is evidence of the excitation of such lines, and data have been obtained for the high-frequency limits of spectra in this region.

This evidence depends upon considerations of a somewhat different character from those dealt with so far. If we consider any typical characteristic X-radiation of an element, for example, the K-radiation, it is found to consist of a number of spectral lines which are denoted by the symbols K_α, K_β, K_γ, in order of ascending frequency. In general there are more than three lines, but we shall adopt the symbol K_γ for the line of highest frequency which is observed, and we shall denote its frequency by ν_{K_γ}. These lines can be excited in an element by a stream either of high-frequency radiation or of high-velocity electrons reaching it. In either case the lines are not excited separately, but the whole group K_α-K_γ appears simultaneously. It is found that there are simple and important restrictions on the radiation frequencies and on the electron energies which are capable of

FIG. 1.

[1] Continued from p. 131.

exciting these lines. Thus it is found that there is a critical radiation frequency ν_c, which is very nearly equal to, but just greater than, $\nu_{K\gamma}$, and unless the incident radiation stream contains components the frequencies of which are at least as great as ν_c, the K series will not be excited. There is a precisely analogous limitation on the electron energies which cause the generation of the characteristic radiations. Thus there is a critical electron energy eV_c, where V_c denotes the critical potential difference through which the electron of charge e has to fall in order to gain this energy, which is connected with the critical frequency ν_c by the quantum relation $eV_c = h\nu_c$, and if the energy of the impinging electrons is equal to, or greater than, eV_c, the characteristic radiations will be excited, otherwise they will not. Furthermore, if we measure the absorption of radiations of different frequencies by the element under consideration, we find that, corresponding to the excitation of the characteristic rays, there is a sudden increase in absorption at the critical frequency ν_c. There is also a discontinuity in the ionisation of the element at the same frequency.

FIG. 4.

There is definite evidence from X-ray phenomena that the critical energy eV_c measures the work which has to be done in removing an electron from its position in the normal atom to a point outside the atom. The characteristic rays are emitted when the gap thus created is subsequently filled up, the different lines arising according to the origin of the electron which fills the gap. If, measured in terms of energy, it is from a near location, we get a low-frequency line such as K_α; if it is from a location near the surface of the atom, a high-frequency line such as K_γ arises.

Thus critical energies such as eV_c give a direct measure, in terms of energy, of the *levels* of the different electrons in the atom. Alternatively, the corresponding critical frequencies ν_c are the *limits* of the relevant X-ray spectra. If we can determine these limits we shall have found the high-frequency ends of the various spectra. While these ends are not, strictly speaking, spectral lines, for the heavier elements at any rate, they are very close to the highest-frequency emission lines in the spectra. Furthermore, according to modern spectroscopic theory, they give us the fundamental data on which the formulæ for the spectral series are based.

It is a curious fact that evidence of the existence of such levels in the gap between what are ordinarily termed the X-ray and the ultra-violet spectra should have been produced independently and almost simultaneously by a number of investigators scattered all over the world. These include Foote and Mohler in Washington, Holtsmark in Christiania, Holweck in Paris, Hughes in Kingston, Ontario, Kurth in Princeton, and myself and Bazzoni in London. While the details of the apparatus used by the different workers vary considerably, the principle involved in most of them can be made clear by reference to Fig. 2 (p. 119). Let the element under test forming the anode A_1 be bombarded by a powerful electron current from the hot cathode F. Then any radiation generated at A_1 can pass between the charged plate condenser P, where any ions present will be removed from it, into the chamber on the left. If the rather complicated apparatus shown in the left-hand chamber is removed and replaced by a plate on which the radiation falls and by a second electrode, the radiation can be detected by the photoelectric electron emission it produces at the plate and measured by the current which flows between the two electrodes, the plate being negatively charged. Let this current be measured and divided by the thermionic bombarding current for a series of different potentials applied between F and A_1; then if there is a sudden generation of characteristic rays from A_1 at some critical potential V_c we should expect an increased rate of rise of the photoelectric current with applied potential to set in at V_c. Thus, briefly stated, the experimental method is to plot photoelectric current per unit thermionic current against primary bombarding potential and to look for discontinuities in the resulting diagram. These discontinuities should occur at the critical potential differences V_c corresponding to the energy levels eV_c and to the frequency limits ν_c equal to eV_c/h.

This general type of method leaves much to be desired, but it seems the most practicable procedure at the present stage of the subject. It is open to the general objection that discontinuities in functional diagrams are often merely indications of faulty experimenting, and the evidence that such discontinuities as are observed are really due to the excitation of X-rays is quite indirect and inferential. It is hoped later, however, to make good this deficiency by supplying a direct test of the frequencies of the radiations generated; for example, by using the magnetic spectroscope which was used for determining the end of the helium spectrum, and by other methods.

Fig. 4 shows the square roots of the critical fre-

quencies of the light elements for K-radiations plotted as ordinates against the atomic numbers as abscissæ. The values for all the elements from magnesium to chromium which are amenable to crystal methods have been determined accurately with crystal gratings by Fricke, who measured the wave-length at the absorption discontinuity. They all lie on a curve which is almost a straight line through the origin, and a few of them are shown thus, x. The aluminium value ⊡ is practically identical with Fricke's for the same element and was obtained by Holweck by measuring the voltage V_c on an X-ray tube for which the absorbability in aluminium of the total radiation is a maximum. This method contains features which, though found separately in the method used by Fricke and in the photoelectric methods, are not common to both, and the agreement will no doubt tend to promote confidence in the photoelectric methods. The points for oxygen (Kurth), nitrogen (Foote and Mohler), carbon (Foote and Mohler, Hughes, Kurth, Richardson and Bazzoni), and boron (Hughes) have all been obtained by photoelectric methods. The hydrogen point △ is the limit of the Lyman series which should correspond to the K level for hydrogen. It will be seen that the hydrogen, nitrogen, and oxygen points practically fall on a smooth curve which is continuous with the curve for the elements from magnesium to chromium. There is some disagreement in the case of carbon, but three of the points are very close to the same curve. The only notable deviation is the low value given by Hughes. The boron value also falls below this curve but there is, so far as I am aware, no known reason why the frequencies should be a smooth function of atomic number for these very light elements.

The next lower critical frequency for any element will presumably be that pertaining to the L group, or the highest L critical frequency if there is more than one. The square roots of a number of such critical frequencies for elements from boron to copper as given by photoelectric methods (boron and carbon, Hughes; carbon, oxygen, aluminium, silicon, titanium, iron, and copper, Kurth) are shown thus, x, in Fig. 3 (p. 120). These frequencies should be somewhat higher than those of the corresponding lines, and it will be seen that the observed points from aluminium to copper are all about the same distance above the broken projection of the curve through the values for the L_{α_1} lines for the elements from zinc to zirconium obtained by crystal measurements. This affords additional justification for extrapolating from the zirconium to zinc L_{α_1} values to the value for the L_α line for aluminium as was done in interpreting Millikan's vacuum grating data. It will also be observed that the values of the limits for boron, carbon, and oxygen given by the photoelectric methods are either very close to the values for the shortest lines in the L spectra found by Millikan or have a somewhat higher frequency. These properties are in harmony with those found in what is more usually regarded as the X-ray region. It should be added that data for elements between sodium and chlorine have been given by Mohler and Foote, which fall on or below the L_α curve as drawn in Fig. 3. These data, however, have been obtained by the electron bombardment of vapours, in many cases of compound vapours, and it is not improbable that the values for these will be different from those for the solid elements. Some of these data also appear to refer to radiation potentials, which correspond to lines, rather than to ionisation potentials, which correspond to limits.

Just as in the case of the L_α lines, the L limits for the light elements from helium to magnesium do not change smoothly with increasing atomic number as do the limits for the heavier elements. In fact the frequency for helium as obtained either by direct determination of the end of the corresponding spectrum or from the ionising potential is higher than that of succeeding elements until carbon is reached.

In the case of a number of elements ranging from aluminium to molybdenum, critical potentials have been observed (by Kurth and by Richardson and Bazzoni) at values corresponding to frequencies well below those which characterise the L spectra. The connexion with the generally recognised X-ray series of the heavier elements has scarcely yet been worked out in sufficient detail for the precise group allocation of some of these to be determined with certainty.

Turning to Fig. 1, C, D, and E show, on the same scale as in A and B, the position of some of the spectral limits given by these photoelectric methods. It will be seen that a majority of them lie in the gap between 16·35 and 17·38 in which so far no spectral lines, either X-ray or ultra-violet, have been detected by grating methods. If the interpretation of these photoelectric determinations as the ends of the various spectra is substantiated, it will have to be admitted that the gap in the spectrum between the ultra-violet and the X-ray region about which I have been speaking is not merely disappearing but has actually disappeared.

Obituary.

PROF. JOHANNES ORTH.

PROF. JOHANNES ORTH, whose death is announced, was born in 1847 at Wallmerod in Nassau. He received his medical and scientific training chiefly at Bonn, where he studied pathology under Rindfleisch, whose assistant he afterwards became. Later, he was appointed assistant to Virchow in Berlin. In 1878 he was appointed professor of general pathology and pathological anatomy in Göttingen and afterwards received the title of *Geh. Med.-Rat.* In 1902, on the death of Virchow, he was elected to the chair of pathology in the University of Berlin, and since then his energies have been devoted chiefly to the development of the Institute of Pathology, which was founded and equipped by Virchow.

Orth was the author of numerous papers on pathological subjects, and also of several books, the two most important of which were his "Compendium der pathologisch-anatomischen Diagnostik," which was translated into English in 1878, and his "Lehrbuch der speciellen pathologischen Anatomie," published in 1893. Orth was undoubtedly a pathologist of great eminence and made many valuable contributions to his subject, but his reputation rested rather on his powers as a teacher and expositor and on his width of knowledge

than on any discovery in a special department. He was essentially a disciple of Virchow and a follower of his methods.

Mr. E. W. Nelson.

The science of oceanography and the scientific study of fisheries have lost a devoted and able worker by the tragic death of Mr. E. W. Nelson, the scientific superintendent of the Fishery Board's marine laboratory at the Bay of Nigg near Aberdeen, who was found dead in his laboratory on the morning of January 17. He had been appointed in September 1921 to succeed Dr. T. Wemyss Fulton in the service of the Fishery Board for Scotland, and he was proving himself a very effective investigator of Fishery problems. He was much liked and respected by his staff, and every one was looking forward to the work that he would do, especially as regards the physical conditions of the sea in their relation to fisheries, for it was in the bearings of physics on biology that he was most interested. He had an ingenious mind, more of the mathematical than of the biological order; though he was a keen naturalist as well. He was particularly well suited for the post that he held and he seemed to be very happy in his work.

Mr. Nelson was educated at Christ's College, Cambridge, and he was working at Plymouth Biological Station when he was chosen in 1910 to be a biologist to the British Antarctic Expedition led by Capt. Scott. He made an elaborate biological survey around the Cape Evans station, and Scott speaks in his "Journals" very appreciatively of his enthusiasm, carefulness, and practical ingenuity. Mr. Nelson was one of the thirteen men who stayed at Cape Evans for a third year under the command of Surgeon Atkinson. During the war Nelson served in the Royal Naval Division.

Mr. Nelson was a pleasant and cheerful personality, very kindly, though fond of an argument, very keen about his own work, but delightfully willing to help others, not wearing his heart on his sleeve, but full of good-will.

Dr. Talfourd Ely.

Dr. Talfourd Ely, whose death was recently announced at the age of eighty-six, was a nephew of Frank Ely, the dramatist, and great-nephew of Sir T. N. Talfourd, author of "Ion." During the greater part of his life he was closely connected with University School and College, London. He was vice-principal and classical tutor at University Hall, classical master at University College School, and secretary of the College. This last post he resigned in order to study archæology at Berlin, where he worked with Ernest Curtius, Kirchof, Robert, Furtwängler, and Waltenbach, and became acquainted with other leading scholars. He travelled largely in Europe, and had an exciting adventure at Olympia with brigands whom he routed. In his later years he was connected with many learned societies—the Antiquaries, Hellenic, Royal Archæological, and others. The literary works by which he will be best known are "A Manual of Archæology" and "Roman Hayling," embodying the results of his own excavations at Hayling Island, besides many papers on archæology.

The death of Miss Charlotte Sophia Burne has left a gap in the ranks of English students of folklore. A native of Shropshire, she edited with additions the collections of Miss G. F. Jackson, which were published under the title of "Shropshire Folklore," one of the best local manuals. Her later years were spent in London, where she became a pillar of strength to the Folklore Society, serving on the council and as president. In 1914 the Society published her admirable "Handbook of Folklore," but the main work of her later days was the collection of a great mass of materials for a new edition of John Brand's "Observations on Popular Antiquities," which was intended to become an encyclopædia of English folk beliefs. When her health broke down the task of editing this work was undertaken by Dr. E. Sidney Hartland.

Current Topics and Events.

The centenary of the death of Edward Jenner on January 26, 1823, was celebrated by the Academy of Medicine in Paris on Tuesday, January 23. At 3 P.M. a large meeting was held at the Academy in the Rue Bonaparte, when the president, M. Chauffard, gave a short address, which was followed by a long, critical, and yet eulogistic speech by M. Lucien Camus, and by communications on the subject of vaccination in detail from MM. Pierre Teissier, Jeanselme, d'Espine, and Sir St. Clair Thomson. The fine large hall of the Academy was crowded, the French Minister of Health, M. Strauss, and Madame Curie being present, in addition to other distinguished people. The busts of Jenner and Pasteur were placed on the right and the left of the platform. After the ceremony a number of mementoes of Jenner in the form of letters by him, and of old cartoons commemorating or deriding vaccination, were shown in one of the halls of the Academy. The president announced that communications in honour of the event had been received by him from learned societies in many parts of the world. Sir Ronald Ross, a foreign associate of the Academy, who represented the British Ministry of Health, handed in also a letter from the president of the Royal Society, and other British societies were represented by Sir St. Clair Thomson and by Dr. R. O. Moon. Sir Almroth Wright, another foreign associate of the Academy, was also present. After the ceremony the president and council of the Academy, in honour of the commemoration, gave a dinner at the Club de la Renaissance Française.

By the will of the late Prof. Emil Chr. Hansen, director of the Physiological Department of the Carlsberg Laboratory, Copenhagen, and his wife, a fund bearing his name was established in 1911 providing

for the award on Prof. Hansen's birthday, May 8, at intervals of about two or three years, of a gold medal bearing his effigy, and accompanied by a sum of at least 2000 kroner, to the author of a distinguished publication on some microbiological subject that has appeared in recent years in Denmark or elsewhere. The medal was awarded in 1914 to Dr. Jules Bordet, Brussels, for researches in medical microbiology, and in 1922 to Dr. M. W. Bejerinck, Delft, for researches in general microbiology. This year it is proposed to award the medal to an author of experimental researches in marine microbiology. The award is made by a committee consisting of the Danish trustees of the fund together with at least two foreign microbiologists. The committee is composed this year of Prof. C. O. Jensen, director, Serum Institute of the Royal Veterinary and Agricultural College, Copenhagen; Dr. Johs. Schmidt, director, Physiological Department of the Carlsberg Laboratory, Copenhagen; Prof. S. P. L. Sörensen, director, Chemical Department of the Carlsberg Laboratory, Copenhagen; Prof. H. H. Gran, University of Christiania, Norway, and Prof. C. A. Kofoid, University of California, Berkeley, U.S.A. Further particulars may be obtained from the president of the Board of Trustees, Emil Chr. Hansen Fund, Copenhagen (Valby).

THE question of training in Illuminating Engineering was discussed at the last meeting of the Illuminating Engineering Society, an introductory paper being read by Mr. C. E. Greenslade and Mr. J. E. S. White. The authors discussed in some detail the planning of courses on illumination at technical colleges, pointing out that special attention should be given to practical applications of light, and that the aspects of lighting considered by architects should be dealt with besides purely technical matters. It was also suggested that occasional popular lectures on the subject would be helpful, and that such lectures would be particularly useful in schools, so that children might grow up with an appreciation of the benefits of good lighting. It was pointed out that there is a need for a suitable text-book for students as most of the works available are somewhat elaborate, and that hints to lecturers on demonstrations and series of suitable lantern slides would also be valuable. The discussion was opened by Dr. F. T. Chapman, of the Board of Education, who suggested methods of improving the treatment of illumination in existing courses, and Mr. Gaster mentioned that the Society had issued a circular to technical colleges offering the co-operation of the Illuminating Engineering Society in the framing of syllabuses and, if necessary, the provision of lecturers. In almost all cases replies received had welcomed co-operation of this kind.

THE presidential address of Capt. H. Riall Sankey to the Institute of Industrial Administration on "Training for Administration in Industry," which was delivered on October 10 last at the London School of Economics, has recently been published in the number of the *Journal of Industrial Administration* for Nov.-Dec., 1922. It gives a brief review of the work of the Institute, and also contains the announcement that, at the instance of its advisory council, the Institute has prepared an examination scheme with the view of the award of diplomas and certificates in connexion with subjects bearing on the administrative side of the work in industry. The scheme is shortly to be put into force, when it is proposed to hold examinations in eight groups of subjects, namely: (1) design, specifications, and inspection; (2) factory planning and plant management; (3) estimating, production methods, and rate fixing; (4) production control (scheduling and regulation); (5) employment administration; (6) materials and purchasing; (7) stores and transport management; and (8) production statistics and costing. The examination questions will be framed in relation to the administrative, in contradistinction to the strictly technical, aspects of the subjects enumerated above. Honours and pass certificates will be issued for each group of subjects, and it is intended at a later date to award diplomas to those who hold the qualifying number of certificates (the precise number has not yet been determined).

AN article which appears over the initials H. B. in *Le Temps* of January 2, discusses the findings of the International Commission which, in September last, visited the sites at Ipswich on which Mr. Reid Moir claims to have found evidence for Tertiary Man. The investigations of the International Commission, which consisted of MM. Lohest, Fourmarier, Hamal-Nandrin and Fraipont (Belgium), MM. Capitan and Breuil (France), Messrs. MacCurdy and Nelson (U.S.A.), and Messrs. Reid Moir and Burkitt, afforded an exceptionally favourable opportunity for a careful examination and discussion of the evidence. The findings of the Commission, therefore, must carry great weight. According to the writer in *Le Temps*, the report presented to the International Institute of Archæology in Paris stated that the members of the Commission were unanimously of the opinion that Mr. Reid Moir's specimens from the base of the "Crag" were genuine artifacts and were found in deposits which were undoubtedly undisturbed, and belonged, beyond question, to the Upper Pliocene. After a careful examination of the characteristics of the specimens, in the course of which all giving rise to any doubt were set aside, the Commission held that they could have been produced by no natural cause and that their distinctive features were comparable with those of Mousterian implements about which there was not the least doubt. The writer concludes that we must inevitably accept the existence of man at Ipswich in the Pliocene period of the Tertiary epoch,—possibly not man himself as such nor even a direct ancestor, but a being who, in virtue of this industry, merits a place in the *genus homo* among the precursors of man; and that the evidence carries back the first appearance of this being on the globe well beyond the 125,000 years at which Osborn dates the beginning of the Pre-Chellean Age.

THE annual report of the National Union of Scientific Workers shows that the Union has increased

its membership to 826 with a corresponding improvement in its financial position. The formation of three special sections with activities connected with Government service, with industrial service, and with universities is probably a step in the right direction. In the first service there is stated to be profound dissatisfaction, partly due to the inadequate position, responsibility and freedom of initiative of scientific workers and partly to the operation of the "Geddes Axe." It is suggested that at the bottom of the discontent of scientific officers in Government departments is the totally inadequate understanding of science by officials, holding executive positions, originally appointed to the Civil Service on examinational efficiency in every side of education but science. The University Section would seem to have a definite function in respect to the teaching, pay, position, and free research hours of university teachers; it seems doubtful policy to merge it into a general education section to consider the whole "tree" from the infants' school to the universities. The Industrial Section has to deal with such matters as the pay, position, and unemployment of scientific workers in industry; the problems are so intricate that any standardising and grading of salaries as well as of the qualifications of those employed would seem impossible. Success is probably bound up with propaganda as to the important economic results likely to ensue from the due employment of properly qualified scientific workers in various sides of economic life. We note in this connexion the amalgamation, so far as their aims are concerned, of the Union with the British Association of Chemists and its friendly co-operation with many other professional bodies.

THE announcement has been made of a gift of 5000*l.* by a donor, who at present wishes to remain anonymous, to the Rowett Research Institute for Animal Nutrition at Aberdeen. This sum is intended to found a library and to provide for making statistical records.

A LECTURE on "Intersexuality and the Determination of Sex" will be delivered by Prof. Goldschmidt, of Berlin, in the Zoology Department, University of Liverpool, on February 15, at 7.30 P.M. An open invitation is extended to all who are interested. Further information can be obtained from Prof. W. J. Dakin, University, Liverpool.

NOTICE is given by the Iron and Steel Institute that the council of the Institute is prepared to consider in March applications for grants from the Carnegie Fund, in aid of research work on some subject of practical importance relating to the metallurgy of iron and steel, or allied subjects, and that special application forms may be obtained from the Secretary of the Institute. The results of research work must be communicated in the form of a report.

A JOINT dinner, to be called the "Ramsay Chemical Dinner," arranged by the Society of Chemical Industry, the Institute of Chemistry, the Society of Dyers and Colourists, the Glasgow University Alchemists' Club, the Andersonian Chemical Society, and the Ardeer Chemical Club, will be held in Glasgow on Friday, February 23. The dinner will take the place of the social functions previously held separately by the various societies in Glasgow and, it is hoped, will promote recognition of the importance of chemistry. Application to attend must reach Dr. J. A. Cranston, Royal Technical College, Glasgow, not later than February 16.

WE have received a copy of a list of the products manufactured by the British Dyestuffs Corporation Ltd., which is made up in the form of a diary. Classified lists of dyes, colours for special purposes, such as soap, film, and foodstuff colouring, are given, and lists of chemicals for research work (under the heading Association of British Chemical Manufacturers), microscopic stains, and indicators, are included. The volume is very convenient, and is a welcome indication of the progress made in the synthetic chemical industry.

THE second course of training for seed analysts will commence in July at the Official Seed Testing Station, Cambridge, and will last four to five weeks. The course is limited to those who are nominated by seed firms, recommended by universities or agricultural colleges, or otherwise show their fitness for such training. At the conclusion of the course, an examination is held which is also open to nominated candidates who have not taken the course of instruction. Applications must reach the Secretary, National Institute of Agricultural Botany, by May 1 next.

THE following lecture arrangements of the Royal College of Physicians of London have been made: Dr. W. G. Savage will deliver the Milroy Lectures on February 22, 27, and March 1. The subject will be "Canned Foods in Relation to Health." The Goulstonian Lectures will be given by Dr. G. Evans on March 6, 8, and 13. The subject will be "The Nature of Arterio-Sclerosis." Dr. A. J. Hall will deliver the Lumleian Lectures on March 15, 20, and 22, taking as his subject "Encephalitis Lethargica (Epidemic Encephalitis)." The lecture hour in each case will be 5 o'clock.

MR. G. A. DUNLOP, keeper of the Warrington Museum, sends his report for the two years ending June 30, 1922. During the latter year the number of visitors amounted to 82,815, being an increase of more than 50 per cent. as compared with the previous year. We infer that the increase consists largely of children, since a serious attempt has been made to bring about a closer connexion between the schools of the town and the museum. A special advisory committee has suggested a scheme for the utilisation of the museum in the teaching of general and local history to the school children. Unfortunately the scheme is not given in the report.

MESSRS. H. F. AND G. WITHERBY announce for publication this month "A Biology of the British Hemiptera-Heteroptera," by E. A. Butler. The work will include a complete list of British families, subfamilies, genera, and species, arranged according to Oshanin's "Katalog" (1912), and many illustrations.

A LIST (No. 31) of second-hand books of science, mainly natural history, botany, and gardening, has just been issued by Mr. R. S. Frampton, 37 Fonthill Road, N.4. Upwards of a thousand titles are given, and the prices asked appear very reasonable.

THE latest catalogue (No. 439) of Mr. F. Edwards, 83 High Street, Marylebone, W.1, is devoted to atlases and maps and books of geographical interest. As is usual with the catalogues issued by this bookseller, the present list contains many rare and scarce items, which are fully described.

MR. E. G. WHITE, the third edition of whose "Voice Beautiful in Speech and Song" was noticed in NATURE of December 30, p. 871, objects to the remark of the reviewer "that I regard the vocal cords 'as strings,' whereas the whole book is written for the precise purpose of showing that they are not strings." In stating that Mr. White regards them as strings the reviewer adopted the argument in Chapter III. of the book, but he did not say that Mr. White actually believed the "vocal cords" to be strings. As to the view that the theory of sinus tone production "is not supported by a particle of evidence," Mr. White refers to evidence "that it is possible to speak and sing when both vocal cords have been excised," but no physiologist would accept this as conclusive. He detaches from the notice of the second edition of his book, in NATURE of April 17, 1919 (vol. 103, p. 124), the words "there is much to admire in this book," but omits to add that the reviewer "J. G. M." entirely rejected his thesis, remarking, "Over and over again he furnishes what he regards as evidence in support of his thesis, but the conclusion, almost invariably, is in the opposite direction." To this it may be added that the supposed evidence never points in the direction of the sinuses.

Our Astronomical Column.

CALENDAR REFORM.—Somewhat of a deadlock has been reached in the matter of calendar reform, owing to the unwillingness of a considerable section to abandon the free week, which has now been running uninterruptedly for some 3000 years, by the introduction of days that would not count in the week or month. Rev. D. R. Fotheringham, editor of the *Chaldæan*, proposes a scheme in No. 17 of that journal which would retain the fixed calendar, without interfering in the least with the succession of weekdays. He proposes to make an ordinary year exactly 52 weeks or 364 days. This could be divided into 4 quarters, in each of which the lengths of the months would be 30, 30, 31 days; or if preferred, there could be 13 months of 4 weeks each: every fifth year (the last digit of which was 0 or 5) would have an extra week; unless the year was divisible by 45, in which case there would be no extra week. There would thus be 8 extra weeks in 45 years, the average length of the year being 365·2444444 . . . days. The true length of the tropical year is 365·242199, so that the error is 0·00224 days, or 1 day in 446 years; this is a trifling amount and could be corrected by dropping the extra week once in 3000 years, in addition to its normal dropping every forty-fifth year. The proposed calendar would satisfy the following desiderata, assuming that the extra week is always reckoned at the end of the year: (1) any particular calendar date would always be on the same day of the week; (2) the interval in days between two dates in the same year would always be the same; (3) the fact of the sequence of weekdays going on unchanged would be likely to remove opposition from ecclesiastical and other quarters. The two chief objections to our present system from the astronomical point of view are the irregular lengths of the months, and the occurrence of the leap-day early in the year. The latter flaw is not due to Julius Caesar, for he made March the first month, as the prefixes Septem-, Octo-, etc., still remind us; so that he saw the advantage of putting the leap-day at the end.

THE POSITION OF THE SOLAR APEX.—The positions derived for the solar apex, or point to which our system is tending, from the study of the stellar proper motions, have been far less accordant than one could wish; it has been found indeed that they differ systematically according to the faintness of the stars the motions of which are utilised. The late Prof. Kapteyn suggested that this discordance might be due to the imperfect correction of systematic errors in the older catalogues; this would affect the proper motions deduced from comparison of these catalogues with modern ones, and the effect on the position of the apex would be greatest for the stars with smallest motions. Now a determination of the apex from the radial velocities of stars is independent of this source of error, and is therefore a useful check. M. J. S. Paraskevopoulos, of Athens Observatory, uses the radial velocities of the stars in Voûte's Catalogue, together with 537 additional ones recently published from Victoria, B.C. His results, given in *Astr. Journ.* No. 813, are:—

	North Stars.	South Stars.	All Stars.
R.A. of Apex	271°·4	272°·2	271°·6 ±3°·0
N. Decl. of Apex	31°·6	29°·6	30°·3 ±3°·0
Sun's velocity km./sec.	20°·7	25°·4	23°·33 : 1°·03

The apex accords well with that usually adopted, but the velocity is somewhat greater.

LOST PLANET RECOVERED.—Planet 132, Aethra, was discovered by the late Prof. Watson of Ann Arbor on June 13, 1873. It was one of 22 found by him between 1863 and 1877; he was not content merely with finding them, but he also determined their orbits and perturbations, and at his death left a trust fund to secure that the necessary calculations and observations should continue to be made on these planets after his death. Aethra appeared to be the most interesting of them all from its large eccentricity and small perihelion distance; however, in spite of constant endeavour it remained lost from 1873 till now. On December 12, 1922, M. B. Jekhowsky, of Algiers Observatory, found a planet of mag. 10·5 in R.A. 5^h $56·1^m$, N. Decl. 18° 27′ with daily motion $-1·3^m$, S. 21′. It was independently found at Simeis on December 19 by M. G. Beljavsky. An approximate orbit by M. Jekhowsky makes it highly probable that it is the lost Aethra, a conclusion which Dr. Luther has reached independently. As further observations are desired, the following predicted positions (from *Astr. Nach. Circular*) may be useful. January 24, R.A. 5^h $11·5^m$, N. Decl. 4° 33′; February 1, R.A. 5^h $10·6^m$, N. Decl. 3° 0′. The period comes out as 3·89 years if we assume 13 revolutions since 1872, but the assumptions of 12 or 14 revolutions would give 4·2ʸ and 3·6ʸ respectively. The elements deduced in 1873 were: Period 3·926 years, eccentricity 0·3314, perihelion distance 1·664, longitude of perihelion 151° 56′, ascending node 259° 40′, inclination 23° 42′.

Research Items.

DECIPHERING CHARRED DOCUMENTS.—Mr. Raymond Davis, of the Bureau of Standards, Washington, finds that the written and printed matter of papers that have been thoroughly charred, as, for example, by being heated in an iron box or safe, may be deciphered by placing the charred sheet in contact with a fast or medium plate for a week or two in the dark and then developing as usual. There appears to be an emanation that affects the plate except where the charred ink acts as a protective coating. It is curious that films need a much longer contact than plates, and that sometimes the effect is reversed unless the film is previously washed and dried.

THE GYPSIES OF TURKEY.—Prof. W. R. Halliday has collected from a wide range of literature an account of the Turkish gypsies in the Journal of the Gypsy Lore Society (3rd series, vol. i., part 4). The conventional estimate of the number of these people in modern Turkey is 200,000, but there is no accurate material for forming any conclusion which possesses the slightest value. The more rigid Osmanli hates them as infidels and dreads them as magicians, and the Christian view of the gypsy's irreligion and genial roguery is illustrated from the folk tales. This feeling is based on the laxity of their religious observances, for in this area religious rule has the added sanction of corresponding with racial or natural cleavage. This thievish habit and way of life have naturally made them unpopular, and it is widely believed in Turkey that they dig up graves and eat corpses, a belief probably based on their habit of eating carrion. It is also stated that they drink annually a secret potion, the composition of which is known only to the oldest and wisest of the tribe, which secures immunity from snake-bite. They are also said to furnish the most expert executioners in Constantinople, but this is scarcely credible. Their employment as bear-leaders is reflected in the dislike shown towards black and brown bears, and to the use of the skins of these bears by furriers in Constantinople.

CERCARIÆ FROM INDIAN FRESH-WATER MOLLUSCS.—Maj. R. B. Seymour Sewell has given an account (*Ind. Journ. Med. Res.*, vol. x., Suppl. Number, 1922) of the anatomy and biology of 52 cercariæ, which he has preferred to designate by numbers as he considers that at present the basis of specific distinction is vague. The majority of the fresh-water molluscs are born in May-August, live for approximately two years, and then die from natural causes. The vitality of heavily parasitised specimens is considerably impaired. The maximal periods of miracidial infection occur in May-June and in September-October, that is, just before and just after the monsoon season. During an examination of nearly 4000 fresh-water snails a double infection—two forms of trematodes developing simultaneously in the same snail—was met with only in eighteen cases, namely in sixteen *Melanoides tuberculatus* and two *Indoplanorbis exustus*, the two most widely distributed species of mollusc in India. Cases are comparatively common in which one form of trematode was found developing from parthenitæ (sporocysts or rediæ) while another was found encysted in the tissues. Maj. Sewell records that on several occasions he observed in sporocysts (producing cercariæ XV., closely related to *Cercaria vivax* Sonsino) the occurrence of miracidia—some of which were still in an incomplete state of development and enclosed in a thin capsule, but others were swimming freely in the cavity of the sporocyst. The sporocyst and redia are not sharply demarcated stages; it is easy to form a graded series beginning with an undoubted sporocyst which appears to be devoid of all structure, passing through forms—in which excretory and certain other organs are partly developed—which might be considered either as sporocysts or as rediæ, and ending with undoubted rediæ with well-developed alimentary canal, a complicated excretory system, definite nervous system and genital organs, and active locomotor processes.

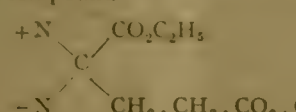
GEOLOGY OF NEW ZEALAND.—The latest view as to the grouping and correlation of the much-discussed strata of New Zealand is embodied in one of the pamphlets conveniently extracted from the *New Zealand Journal of Science and Technology* (vol. 5, No. 1, 1922). In this Mr. P. G. Morgan, director of the Geological Survey, gives geological maps of both the great islands, printed clearly in black and white, on a scale of 1 inch to 40 miles. If these were not so economically printed back to back, they might well be mounted by their fortunate possessor and coloured according to the international scheme. The divisions of the Maitai systems (formerly held to be Triassic and Jurassic, but now shown to be Permo-Carboniferous) are still undecided; but it is clear that the grouping of these rocks on the geographical axis of the southern island is not a tectonic feature, their general strike being north-westerly. In the epoch of their deposition, New Zealand lay on the margin of Gondwanaland, and it seems reasonable to suggest that the strike of the Maitai systems, when they came to be folded, was determined by the pressures from the south that crumpled the beds in Jurassic times in the coast-ranges of the Cape Province of S. Africa. As Mr. C. A. Cotton has pointed out ("The Outline of New Zealand," *Geographical Review*, vol. 6, p. 320), the present form and features of New Zealand have been largely determined by faulting, with the formation of blocks of uplift and depression. The dominion is developing its culture on a mere fragment of land left among the deeps.

PALÆONTOLOGICAL RESEARCH IN CHINA.—The third Asiatic Expedition of the American Museum of Natural History has been co-operating with the staff of the Geological Survey of China, and, in view of the interest taken in their joint researches, Mr. J. G. Andersson, with his colleagues of the Chinese Survey, have issued a brief summary of the results of the Survey's operations so far as carried out (Bull. Amer. Mus. Nat. Hist., xlvi. art. 13). The fossil invertebrates are being worked out by Dr. A. W. Grabau, now palæontologist to the Geological Survey of China. At present these have been obtained almost exclusively from the palæozoic deposits, and will be described in the near future in a work devoted to Chinese palæontology, initiated by Dr. V. K. Ting, the director of the Geological Survey of China, and entitled "Palæontologia Sinica." Of considerable interest is the discovery of the first Eurypterus in China in the coal measures of the Kaiping basin in strata of Lower Permian age. Coal deposits are plentiful and range from Palæozoic to early Tertiary. By far the most interesting among the plant beds of China are the Permo-Carboniferous coal series, while those of the Jurassic of northern China come next in importance, and the Oligocene flora of Fushun, in Fengtien, is the most representative of the Tertiary beds. Of the fossil vertebrates the principal description hitherto has been that of Schlosser, who, however, procured his material from Chinese medicine shops. Mr. Andersson has now

brought together extensive collections. The Hipparion clays of northern China prove the richest deposits so far. The north China loess but rarely contains fossils. One of the commonest is the egg of a big ostrich, *Struthiolithus chersonensis*. There is also an elephant, doubtfully referred to *Elephas namadicus*. No undisputed proof of the existence of Palæolithic man has as yet been obtained, nor of any Older Neolithic culture.

INDUCTION MOTORS AS SYNCHRONOUS MACHINES.—In the *Journal of the Indian Institute of Science*, vol. 5, part 4, p. 37, there is an interesting and useful paper by S. V. Ganapati and R. G. Parikh on induction motors used as synchronous machines. From the point of view of the engineer of the supply station the large "wattless" current taken by induction motors is a serious drawback to their use, and methods are sometimes employed to penalise consumers in proportion to the amount of wattless current they take. The authors have experimented on induction motors by supplying their rotors with direct current and thus converting them into synchronous machines. They found that they were more unstable than ordinary synchronous motors, as a relatively small decrease in the exciting current caused them to fall out of step. They find also that, for heavy loads, this method involves a sacrifice of efficiency and only a slight diminution of the wattless current. It is also necessary to adjust the excitation to the load and hence it is unsuitable for fluctuating loads. The advantages of synchronous operation are only pronounced at times of light load.

POSITIVE AND NEGATIVE VALENCES.—The *Recueil des Travaux chimiques des Pays-Bas*, which was founded in 1882 and of which the forty-first volume has just been completed, is now to assume an international character, since it has been arranged that the *Recueil* will henceforth contain articles in French, English, and German. With this announcement there has been circulated a double number for September and October 1922, in which this policy has been put into operation. The issue contains the papers read at an International Congress of Chemistry held at Utrecht on June 21-23, 1922. It includes 14 papers, of which three are in English, four in French, and seven in German. The three Russian authors contribute two papers in French and one in German, while the Swiss contribution also appears in French. Perhaps the most interesting of these papers is the one in which Prof. W. A. Noyes discusses the question of positive and negative valences. He puts forward as evidence of the real existence of oppositely polarised atoms the production of an optically active form of the diazo compound



where it is almost impossible to find a satisfactory explanation of the optical activity except by supposing that the two nitrogen atoms differ sufficiently to destroy what would otherwise be a plane of symmetry of the molecule. The question of free radicals is also discussed in two papers by Prof. Walden and Prof. Schenck.

STRESSES IN BEAMS, RINGS, AND CHAINS.—The honorary members' lecture to the Junior Institution of Engineers for the year 1922 was delivered by Prof. E. G. Coker, who chose for his subject "that branch of the elasticity and strength of materials which deals with the stress distributions in curved beams, rings, and chain links." The lecture is printed in the Journal of the Institution, Part 6, vol. xxxii., and forms a valuable résumé of the application of the optical properties of transparent bodies to the determination of the stresses in these bodies. It is pointed out that in plain stress, all materials which fulfil the primary conditions of elasticity are stressed in precisely the same manner under similar conditions of shape and loading, and so the stresses can be found by observation on transparent material like nitro-cellulose. The cases dealt with are the straight beam subjected to bending moment (to show that when the beam is unsymmetrical about the plane of bending, the usual formula giving the stress in terms of the change of the curvature is not correct), discontinuities in beams, short beams, beams of constant curvature under uniform bending moment (as being of theoretical interest), the crane hook, circular rings, elliptical link with and without stud, circular link with straight sides, and various kinds of piston rings. The mathematical treatment is indicated, while in two appendices is given in brief the mathematical theory of stresses in curved beams (Andrews and Pearson) and of stresses in curved links (Pearson-Winkler theory). Prof. Coker's lecture is a record of important researches on an important subject, to which he and his assistants have made very considerable contributions. It is of interest to note his opinion "that the stress distribution in complicated bodies . . . is one which still demands a very large amount of study by analysis and experimental research."

THE FINITISTIC THEORY OF SPACE.—The logistic mathematicians are very boastful of their claim to have solved the paradoxes of Zeno by their new definition of infinity as a compact series. Their doctrine, however, is not unchallenged. Dr. Petronievics in his "Principien der Metaphysik" has put forward the theory of the finiteness of the number of points in space. His argument is set forth from the point of view of mathematics, metaphysics, and also what he terms hyper-metaphysics, and historically it is claimed to be as old as Pythagoras. A clear, concise, and easy account of the doctrine is given in "Die Lehre vom diskreten Raum in der neueren Philosophie," by Dr. Nikola M. Poppovich (Wilhelm Braumüller, Wien und Leipzig, 1922). It is the thesis for the doctorate of philosophy awarded by the University of Berlin the year preceding the war. Dr. Poppovich reviews the whole problem of the principle of the continuity and discreteness of space from ancient to modern times. The theories fall for him into three types. The first he names the infinitistic realistic, it includes Bolzano and Cantor; the second, the infinitistic idealistic, includes Leibniz and Kant, and in the nineteenth century is represented by Renouvier; the third is the finitistic realistic doctrine of Petronievics. According to this last there is a clear distinction between real and unreal points. The essence of the doctrine would seem to be that the compact series which separates two points is not a series of real points in the sense in which the two definite points are real. The compact series has no other function than that of holding the two real points apart. Thus, to take our own illustration (if we are rightly interpreting the doctrine) the integers 1, 2, in the numerical series are separated by an infinite, *i.e.* a compact, series of fractions, but this series is unreal, *i.e.* imaginary; it serves the single purpose of preventing the two units falling into one identity. The theory leads Dr. Petronievics to affirm the absoluteness of Euclidean space.

The Lourenço Marques Meeting of the South African Association.

THE twentieth annual meeting of the South African Association for the Advancement of Science was held at Lourenço Marques, in the Lyceu, on July 10-15, under the presidency of Dr. A. W. Rogers. The meeting was well attended and was very successful. About fifty papers were read. An official welcome was given by the High Commissioner for Moçambique and the Mayor of Lourenço Marques. There were various visits and excursions to places of local interest, both on the Bay and inland, and an official banquet was given to members at the new Polana Hotel.

A popular lecture, illustrated by lantern slides, was given by Mr. C. Graham Botha, Keeper of the Archives at Cape Town, on "The Early Development of South Africa."

The South Africa medal and grant were awarded to Dr. I. B. Pole Evans for his contributions to botanical science in South Africa.

The presidential address by Dr. Rogers dealt with "Post-Cretaceous Climates of South Africa." Four types of evidence on which recognition of former climates depend were discussed. These were the character of the rocks during the period concerned, the shapes of the land surface resulting from long duration of more or less constant climatic conditions, the distribution of animals and plants, and the historical records of man; the lithological evidence is the most important for all but relatively recent times. Each of these factors was considered in detail as regards South Africa, the evidence being considered from post-Cretaceous times only. Historical records of the past climate in South Africa apply closely to present-day conditions, allowance being made for the progressive settlement of the country. From personal survey work Dr. Rogers concluded that in certain districts no deterioration of climate or marked loss of water has taken place during the last fifty years. The various lines of evidence point to the conclusion that during post-Cretaceous times the climate of South Africa has fluctuated within rather narrow limits; that there has not been a Pluvial period, if by that term is implied a long period of much greater rainfall over the whole country; that a general lowering of temperature in the Pleistocene may have given the Karroo and Southern Kalahari rivers longer periods of flow, but that this more humid era in those regions had come to an end long before human evidence can be drawn upon for an account of it; and that South Africa, like North Africa, the Americas and Australia, bears evidence to a shifting of the climatic belts in the Pleistocene and subsequent times.

The presidential address to Section A on "The Rôle of Astronomy in the Development of Science," was given by Dr. M. A. Peres, Director of the Campos Rodrigues Observatory, Lourenço Marques. He summarised ably some of the chief discoveries and laws in astronomical science, and showed their influence on subsequent research in other branches of physical science. Thus, astronomical observations led to the formulation of the laws of Newton, which opened a vast field of other researches. Similar astronomical observations leading to the work on the velocity of light were the first step towards wireless telegraphy. The indebtedness of optics especially, to astronomical research, was also indicated, and it was pointed out that the chief confirmation of Einstein's theory was dependent on astronomical observations.

"The Influence of Mineral Deposits in the Development of a Young Country" was chosen by Dr. E. T. Mellor as the subject of his presidential address to Section B. This was first illustrated by reference to the Tsumeb Mine in South-West Africa and Broken Hill in Rhodesia. The Tsumeb Mine brought about the building of a railway from the coast to the mine, 350 miles away. The Broken Hill Mine practically determined the course of the main line of the Cape to Cairo railway. The railway system of the Union of South Africa has been influenced by the goldfields of the Witwatersrand. The tracing of the extension of these gold reefs eastwards, the location and exploration of new coalfields, and systematic boring for possible oilfields, all depended on an adequate geological survey. The extension of the Witbank coalfield, though proved and ready for easy exploitation, is suspended because of lack of transport and a market. The connexion of mining developments with research in other sciences was considered, and it was shown that in the gold industry South Africa possesses a field sufficiently extensive and stable to exert more than a temporary influence on the country generally.

The presidential address to Section C was given by Prof. D. Thoday, and dealt with "Carbon Assimilation" in plants. The great advances in the knowledge of the subject due to the work of Blackman in Cambridge and Willstätter in Berlin were summarised, attention being directed to the work done on pigments. The rôle of iron and of magnesium were also discussed. The application of the subject with special reference to South African conditions was detailed. The plants of the open veld are exposed to the full blaze of the sun through most of the year, and this is more than sufficient to enable an ordinary green leaf to assimilate all the carbon dioxide that it needs. Paler green or golden leaves demand more intense light than dark ones for their full activity. Consequently, veld plants have paler leaves, and in extreme cases the leaves are almost greenish yellow. Particulars of internal structure affecting depth of colour were also discussed, as were leaf forms and patternings, and it was emphasised that such features are not merely adaptations to a dry climate but that their effects on photosynthesis of carbon dioxide are probably of equal significance.

The presidential address to Section D was delivered by Dr. Annie Porter, her subject being "Some Modern Developments in Animal Parasitology." After a general introduction dealing with degrees of parasitism, specificity and the like, recent advances in protozoology were first considered. Attention was directed to the conflicting opinions as to the existence of races of *Entamœba histolytica*. The work of Taute and Huber on the non-identity of *Trypanosoma rhodesiense* and *T. brucei*, as shown by direct inoculation of the human subject with game trypanosomes, was discussed, and attention was directed to work on induced herpetomoniasis in vertebrates. Flagelloses of plants were described, especially those due to herpetomonads, some of which had been proved capable of infecting mammals; also the spirochætes, amœbæ, and other parasitic Protozoa found in plants and their reactions on their hosts were noted. Recent work on neuromotor apparatus in Protozoa, and on various organisms and filterable viruses associated with infective (spirochætal) jaundice, trench fever, and typhus were discussed. In helminthology the interesting life-histories of schistosomes in various snails, of Clonorchis in snail, fish and man, of Paragonimus in snail, crab or crayfish and man, and recent work

on the life-histories of such organisms as *Fasciolopsis buski*, Heterophyes, Ascaris, and Strongyloides were detailed. In entomology hyperparasitism and its possible applications, Stomoxys as the transmitter of North African trypanosomiasis, the rôle of *Trombidium akamushi* in river fever in Japan, and the part played by various ticks in a peculiar form of human motor paralysis in America were among the topics discussed. In conclusion, some of the sociological applications of parasitology were mentioned, and the need of more provision for research work was emphasised.

The presidential address to Section E, by Senator A. W. Roberts, related to "Certain Aspects of the Native Question." The changes in national life and in the mental attitude of the native, due to gradual disappearance of the old tribal system, were discussed. The growing desire for individual possessions and the movement among the younger generation of Bantus for racial solidarity were considered as natural steps in the evolution of a race. The immigration of the native into industrial areas, the change in habit and in outlook, the bad features of location life, and the need for proper housing were emphasised. The history of native education was traced, and it was shown that the system in vogue at present had served its purpose. New ideals in native education should be in the direction of material progress, better means of agriculture, and village and home industries. The principles of good citizenship need impressing on the native as well as on the white. The extension of opportunities of work for educated natives and their feeling regarding their present economic limitations were discussed. The political future of the native and the extension to other areas of the system successful in the Transkei were considered. Mutual understanding between white and native is necessary.

The presidential address of Dr. J. Marius Moll to Section F was entitled "Certain Mental Disorders which may be regarded as Preventable." Mental disorders were considered in two groups—the "intoxication" psychoses caused by a poison in the wide sense and producing changes in the brain, and "germ" or "functional" psychoses where no causative poison occurs, no microscopic alterations, and no dementia. The intoxication psychoses due to other illnesses, *e.g.* enteric, were briefly noted. Alcoholic insanity, with its great danger of recurrences, was considered. In the case of inmates of native mental hospitals in South Africa, dagga (*Cannabis indica*) may be an important etiological factor. Syphilis is decreasing in South Africa. Malaria is not only a factor in some cases of insanity but also in intellectual retardation and enfeeblement in the country. Dementia precox is serious, 21 per cent. of the admissions to mental hospitals in the Union being due to this. The work on internal secretions and on psychopathology was mentioned. In the germ psychoses the personality of the patient is the main factor. The rôle of sex-complexes was shown to have been overrated by Freud and some of his followers. The reciprocal reaction between the personality and the circumstances of a patient had to be reckoned with. The need for study and adoption of the principles of mental hygiene was urged. Heredity was a serious factor in insanity. If segregation and non-propagation of the mentally unfit were enforced the future incidence of this condition would decrease by 50 per cent.

It is only possible to notice some of the interesting papers read before the various sections. Nearly half of the papers were contributed to Section D. In Section A a useful paper was read by Mr. R. H. Fox on the waterworks department of the Antofagasta (Chile) and Bolivia Railway Company.

In Section B, Mr. B. J. Smit contributed a paper on his investigations of different methods of testing Babcock milk-bottles; the volumetric method was preferred. Mr. C. O. Williams continued his account of experiments on the chemical control of cattle-dipping tanks; the addition of coal-tar disinfectants to arsenical dips was uneconomical. Dr. P. A. Wagner described various specimens of Descloizite from South-West Africa.

In Section C, Prof. G. Potts continued his account of experiments on the pollen of the pepper tree as a cause of hay fever in Bloemfontein. Prof. J. W. Bews and Mr. R. D. Aitken discussed the measurement of the hydrogen ion concentration in South African soils in relation to plant distribution. Mr. Aitken also described the effect of slope exposure on the climate and vegetation of a hill near Maritzburg. Mr. A. J. Taylor dealt with the composition of some indigenous grasses both from the chemical and the botanical aspects. The economic values of the grasses were indicated.

In Section D, Mr. J. Sandground read a short paper on *Aphelenchus phyllophagus*, parasitic in chrysanthemums, noting its effects in South Africa. Prof. E. H. Cluver dealt with the effect of temperature on the rate of growth in young animals; the greatest increase in weight occurred during the cooler months. Mr. A. D. Stammers described keratomalacia among rats suffering from deficiency of vitamin A. Dr. C. P. Neser sent an interesting paper on the blood of equines. Prof. E. Warren described and illustrated the early stages of development of the non-aquatic tadpole of *Anhydrophryne rattrayi*; predetermination of sex occurred in the eggs. Prof. J. E. Duerden discussed old and new views on the origin of feathers from scales. Prof. Duerden and Mr. R. Essex described the degeneration of limbs in species of Chamæsauran lizards. Prof. Duerden and Mr. V. FitzSimons recorded a series of variations found by them in the tenth rib of the penguin. Dr. F. G. Cawston described and exhibited specimens of Mollusca from lagoons in Natal. Prof. H. B. Fantham continued his account of some parasitic Protozoa found in South Africa, noting the occurrence of herpetomonads in cabbage plants. Prof. Fantham and Miss E. Taylor described the continuation of their researches on Protozoa found in some South African soils. Mr. C. B. Hardenberg discussed economic entomology in Moçambique. Dr. L. Soromenho described, from the hygienic point of view, various native wines and spirits made in Moçambique. Dr. M. M. Prates presented a contribution to the study of human parasitology in Moçambique, and he also described the various diseases of the eyes occurring there. Mr. J. Hewitt discussed ancient southern land connexions of Africa. The section considered favourably a draft bill for the establishment of a national park and game reserve under the direct control of the Union Government.

In Section E, Rev. C. Pettman contributed further remarks on Hottentot place-names. Rev. H. L. Bishop read interesting papers on Si Ronga proverbs and folklore and on the descriptive complement in Si Ronga. Madame V. Gomes discussed the N and L intervocalic in archaic Portuguese. Prof. W. A. Norton dealt with Dr. Theal's historical work on South-East Africa, and pleaded for a continuance of such work. He also exhibited a glossographic map of South Africa.

In Section F, Mr. C. G. Botha illustrated the early history of the Cape Province by a consideration of

Dutch place-names. Mrs. Mabel Palmer discussed some Australian proposals for a wage varying in proportion to the size of the family. Mr. F. S. Livie-Noble outlined some practical applications of modern psychology. There was a discussion, opened by Captain A. Cardozo, on the currency problem in Moçambique.

The next annual meeting of the Association will take place in July 1923 at Bloemfontein, under the presidency of Prof. J. D. F. Gilchrist. H. B. F.

Mental Character and Race.

IT is a commonplace of anthropological study that, in investigating the customs of primitive races, the difference in level of culture between observer and observed entails a difference in mentality and outlook which it is one of the aims of anthropological training to overcome. But it is also a matter of common observation that this same difference exists, if in a lesser degree, between peoples at the same stage of civilisation, and even between individuals or groups of individuals forming part of the same people or nation. The works of travellers, geographers and historians, both ancient and modern, abound in characterisations of the mental qualities of the various peoples of the world, both civilised and uncivilised; but when the ethnologist comes to the investigation of the problem of racial differences in mental qualities, he is confronted with a two-fold difficulty. On one hand he is, at present, for the most part, dependent upon empirical observation from which it is difficult to eliminate the personal factor, and, on the other hand, it is not clear how far, if at all, mental characters can be correlated with the physical characters upon which the ethnologist bases his classification of races. In the solution of this problem it is essential that the anthropologist should secure the co-operation of the psychologist, and it was with this object that a discussion on "Mental Character and Race" was held in a joint session of the Anthropological and Psychological Sections at the meeting of the British Association at Hull in September last.

The discussion was opened by Prof. J. L. Myres, who said that the principal consideration to be submitted to psychologists and ethnologists alike was that in many individuals in any modern society of mixed ancestry, dispositions and faculties differ. Such mental qualities are inherited like physical qualities and characters. It might be assumed that they stood in some direct relation to some element in the nervous system. Further, some mental qualities seemed to be associated with some physical characters, as for example a "fiery" temperament with red hair. Some of these physical characters are racial, or (like red hair) seem to result from crossing of racial elements. The analogy from the artificial selection of the breeds of domesticated animals indicates that it is possible to enhance or combine mental qualities. It did not always happen that the individual exhibited the characteristics desired, as in the case of the "gun-shy" pointer, and the "gun-shy" member of a military family. It would appear, however, that the hypothesis of correlation and transmissibility of psychical characters stands the test of practice in domesticated animals, the nearest analogue to the long domesticated animal man, a single species broken up into strongly marked racial strains.

Prof. Myres went on to point out that the older ethnologists characterised racial types by mental as well as physical characters, and quoted as an example the character of the Northern Mongols in Keane's "Man, Past and Present." He pointed out that such a characterisation included: (*a*) a description of mere psychological reactions to external stimuli conceived as characteristic of the racial strain and capable, like brachycephaly, of being used to refer an individual to his racial type; (*b*) a description of social reactions (*e.g.* "sense of right and wrong") in which a social, cultural element was introduced. The individual has a post-natal experience as well as a pre-natal equipment, and in investigation it might be difficult to eliminate disturbing factors. Prof. Myres stated, however, that he himself had found that the offspring of British fathers and Greek mothers brought up in a Greek environment differed as markedly from pure Greeks in their attitude towards discipline and labour as they did in physique, temperament closely following breed.

Modern ethnology, relying on analogue and experiment, had made most progress in the department of sense perception; but even here one of the first results had been to show how intimately the social factor was involved, as for example in inducing a native to give a fair trial to an experiment beyond his social horizon and in eliminating the disturbing factor of an inadequate language, *e.g.* in the case of colours.

In summing up the problem, Prof. Myres said that the ethnologist, and, in particular, the social anthropologist, must define more clearly the elementary terms in their characterisation, while the psychologist must go further in laboratory work on such complex manifestations as the "sense of right or wrong," irrespective of race or breed.

Dr. C. S. Myers, president of the Psychological Section, said that the chief determinants controlling mental characters were heredity and environment. On the physical side environment—climate, temperature, food supply, and the like—acted directly and indirectly, especially on the internal secretions which affect the functions of the emotions. Environment must have played an important part in producing such differences as distinguished Americans, Australians, and New Zealanders; but it was not known with certainty how these differences came about, nor how permanent they were likely to be. Different parts of the same country exhibited distinguishing characteristics. In England, for example, Yorkshire and Wales had for long been noted for musical ability. What did this mean in terms of race? Where there was lack of ingenuity or artistic skill, were these qualities latent, awaiting the encouragement of a more favourable environment? Rivers had shown that contact of culture produced something new, and apparently the same applied to an individual.

Dr. Haddon said the results of the psychological observations made by the Cambridge Expedition to the Torres Straits had been largely negative. A scheme should be worked out for the observation of the emotional content of the attitude of primitive peoples towards their own ceremonies.

Dr. Cyril Burt said that experimental tests of intelligence and other inborn mental capacities usually yield a correlation of about 0·5 between the performances of parents and those of their children. Thus, mental qualities seem to be inherited to much the same degree as physical. Small but distinct and constant differences are discernible between the averages for different nations and races. On the whole, however, individual differences tend almost to swamp the group differences. On the temperamental side,

group differences are possibly larger; and there is some evidence to show that differences of so-called temperamental type may be associated with racial differences (*e.g.* the so-called "objective" type with Nordic physical features and the so-called "subjective" type with Mediterranean).

Mr. Fallaize pointed to the persistence of certain mental qualities in different races noted by the older travellers and historians.

Dr. Shrubsall said that he had observed that the children of Chinese fathers and English mothers in London schools, brought up in much the same environment as English children, were intellectually as quick as the latter but showed no inclination to take part in games. Among English children differences in pigmentation appeared to be associated with differences in direction of aptitude.

In summing up the discussion, Mr. H. J. E. Peake, the president of the Anthropological Section, said that while no very definite conclusion had been reached, it was clear that the aim of investigators must be to eliminate the personal element, while psychologists should endeavour to break up mental characters into such simple factors as might be subjected to reaction tests, as courage had been shown to be the reaction to danger.

Scientific and Industrial Research.[1]

THE Committee of the Privy Council for Scientific and Industrial Research has issued its seventh annual report, with that of its Advisory Council, covering the year 1921–1922. The first few pages deal with the income and expenditure of the Department of Scientific and Industrial Research, and with its efforts to observe the spirit of national economy. It is pleasing to record that the Geddes Committee on National Expenditure has not found it necessary or expedient to recommend any reduction in the estimates beyond that proposed by the Department itself. The total expenditure during the financial year 1921–1922 was nearly 525,585*l.*, made up of 190,024*l.* at the National Physical Laboratory (nearly 100,000*l.* being recovered in fees, etc.), 46,616*l.* at the Fuel Research Station, 57,423*l.* for the Geological Survey and Museum, 10,323*l.* at the Building Research Station, 17,750*l.* at the Low Temperature Research Station, 21,464*l.* on the work of the Co-ordinating Boards and Committees, 5988*l.* on minor research programmes, 86,355*l.* (from the million fund) in grants to the Research Associations, 8287*l.* in grants to other bodies, 43,793*l.* in research studentships, and 37,561*l.* on administration at headquarters.

By far the major portion of the report, however, deals with the plans and achievements of the various research organisations associated with the department. Considerable interest will be awakened in the twenty-four industrial research associations, twenty-two of which are already in active operation. A few of these associations have now been in existence long enough to have produced results of practical value, examples of which are given. Thus, the British Portland Cement Research Association has been able to effect considerable economies in fuel in many works through the results of its researches on rotary kilns and advice on scientific management. The British Scientific Instrument Research Association has introduced a new polishing powder and an abrasive for the production of lenses and prisms, by means of which grading and hand work are eliminated, and much time is saved. The British Cotton Industry Research Association has produced an instrument for the testing of yarns, continuous lengths being examined instead of short pieces as hitherto, with the result that important variations have been revealed in certain yarns, which are introduced by the method of spinning. Finally, the Linen Industry Research Association has developed a pedigree strain of flax seed which gives much higher yields of fibre than any existing variety, and has discovered methods whereby flax and hemp may be distinguished at all stages of manufacture. It is obvious that these are not isolated pieces of work, but rather the first-fruits of a considerable harvest which has been patiently husbanded by the research associations, and it is no secret that a mere catalogue of the further results which have been published in the scientific press since the report was written would occupy considerable space.

The value of co-operation between the research associations is emphasised again. Several instances are mentioned of two or more associations attacking a common problem, the most interesting cases being those in which the participants are respectively consumers and producers of the materials investigated. Mutual efforts of this kind must result in improvements in useful commodities and possibly in a lowering of the cost of production.

Considerable space in the report is also devoted to the work of the co-ordinating research boards, which more directly serve national interests. Attention is directed to the commendable willingness of the Service departments to enlist the co-operation of outside bodies and to arrange for the open publication of the results of the work undertaken when these are of sufficient general interest. The co-ordinating research boards consider an enormous variety of problems in physics, chemistry, and engineering, including radio-telegraphy, the liquefaction and storage of gases, the deterioration of fabrics used by the fighting services, adhesives, and lubrication, and the report mentions several of the results obtained. Furthermore, public interest should be aroused in the work of the Fuel Research Board, which has issued most valuable information in a number of publications which have already been noted in these columns; *e.g.* in NATURE of November 25, 1922, p. 718, when the report on experiments on low temperature carbonisation was discussed. The work of the Food Investigation Board is also of common interest, and important advances are reported in the study of cold storage, and the bacteriology of canned meat and fish.

A useful discussion of the terms "pure" and "industrial" research is given, the distinction being mainly a question of the source from which the impulse to the conduct of research is derived. It has been all too common on the part of workers engaged in "pure" research for a very few problems to be pursued through all inviting ramifications, with the result that while certain small areas may be very thoroughly cultivated, the worker remains unimpressed by the vastness of the unexplored territory outside his own subject. The problems facing any one industry are much more varied than is frequently imagined, and the gaps in scientific knowledge which they reveal are often astonishing. For example, the Cotton Research Association finds it necessary

[1] Report of the Committee of the Privy Council for Scientific and Industrial Research for the Year 1921–22. (Cmd. 1735.) Pp. iv+123. (London: H.M. Stationery Office, 1922.) 3s. net.

to study the fundamental properties of single cotton hairs, the existing data being very scanty; the Photographic Research Association is investigating the properties of silver haloids and gelatin; the Portland Cement Research Association is endeavouring to ascertain the exact nature of the compounds constituting Portland cement; and the perfection of an abrasive and a polishing powder by the Scientific Instrument Research Association followed an investigation of the primary phenomena of grinding and polishing.

Two interesting examples of the interplay of "pure" and "industrial" research are given. On one hand, the knowledge gained by an investigation into the fundamental physiology of living and dead food-stuffs has cleared up the mystery of the "brown-heart" of apples, which has caused severe losses in shipments from Australia. The "disease" has been attributed to insect injury in the orchards, but is now known to be due to the effect of the carbon dioxide engendered by the fruit itself in the badly ventilated holds of the ships. On the other hand, the study of the structure of coke at the Fuel Research Station has led to the conclusion that carbon in this form is a vitreous substance of great hardness, which profoundly affects the problem of the allotropy of this element. Some of the results obtained were described in NATURE of January 27, p. 133.

The industrial research associations are comparatively young bodies, but such as have already issued reports on investigations undertaken have given ample justification for their existence.

The Gold Coast Survey.

THE Survey Department of the Gold Coast, which was closed during the war, was reopened in 1920 by the present Governor, Sir F. G. Guggisberg, who had formerly initiated the survey of a considerable portion of Nigeria. The long cessation of survey work on the Gold Coast had left matters in a backward state. To cope with immediate needs the department was strengthened, and it is believed that by 1924 the lost ground will have been regained and the country will be provided with a modern survey department. Lieut.-Col. R. H. Rowe is in charge of the new department, with Maj. G. H. Bell at the head of the field-work. The survey parties are organised in three sections which refit in England from July to September, when they leave for the Gold Coast in order to take full advantage of the "dry" season. Each section is divided into several completely equipped "field camps," under European surveyors.

The country that has been surveyed during the last two field seasons has been mainly dense tropical forest, presenting great difficulties to the surveyor. Lines must often be cut through the forest in order to reveal the surface features. Even in the dry season there are climatic difficulties. From December to March the harmattan frequently occurs and obscures the vision. At other times the dry winds warp and split the woodwork of boxes, instruments, and tent-poles. The surveyors, of course, have to face malaria and other forms of sickness.

An important part of the new Survey Department is the Survey School at Odumase for the training of native surveyors. A three years' course in the school, followed by four years' service with the Government, qualifies a native to start in private practice. There are apparently good openings in this profession for African surveyors.

FIG. 1.—A field survey camp on the march.

In addition to the Topographical branch of the survey there are two others—the Cadastral and the Records and Reproduction branches. In the Cadastral branch a great deal of work on land surveys and town plans has been done. The Records branch is gathering material for gazetteers and handbooks of the country, and the Reproduction section is engaged in printing road-maps, statistical maps, and diagrams. The topographical sheets of the survey on a scale of 1 to 125,000 are not being printed in the colony, but by Messrs. W. and A. K. Johnston (see NATURE, November 11, p. 647), to whose courtesy we owe the accompanying illustration (Fig. 1). About 15,000 square miles have already been surveyed, and it is expected that the present season's field-work will practically complete the maps of the Gold Coast Colony itself and also a large area in Ashanti.

Paris Academy of Sciences.

BONAPARTE AND LOUTREUIL FUNDS.

GRANTS for research from the Bonaparte and Loutreuil funds have been allocated as follows:

Bonaparte Fund.—Six applications have been examined and two grants are recommended:

(1) 5000 francs to the Association lyonnaise pour le développement des recherches de paléontologie humaine et de préhistoire, for carrying on excavations in the celebrated prehistoric deposits of Solutré.

(2) 2000 francs to Charles Le Morvan for completion of the publication of the systematic and photographic map of the moon.

Loutreuil Fund.—Thirty-one applications were considered and grants were recommended as follows:

(1) The National Museum of Natural History: 8000 francs to Désiré Bois for the publication of the first two parts of a guide to the collections of cultivated plants at the museum.

(2) The central council of observatories: 1000 francs to the National Observatory of Besançon for the acquisition of an Abraham oscillograph; 3000 francs to Auguste Lebeuf, for the purchase of an oven required for researches relating to the simultaneous action of temperature and pressure on chronometers, for aviation purposes.

(3) Council for the improvement of the École polytechnique: 6000 francs to Alfred Perot, for the construction of an apparatus designed for the verification of a formula given by the Russian physicist, W. Michelson.

(4) National Veterinary School of Alfort: 1600 francs to the school, which, together with balance of 8000 francs remaining from the sum granted in 1920, is allotted as follows:—5000 francs to Adrien Panisset and Jean Verge, for researches on the chemicotherapy of the infectious diseases of domestic animals; 2000 francs to Edouard Bourdelle and André Rochon-Duvignaud, for researches on vision in animals; 2000 francs to Albert Henry and Charles Leblois, for researches on the etiology, pathogeny, and treatment of parasitic cutaneous affections of domestic animals; 600 francs to Gabriel Petit, for the purchase of a microscope.

(5) National Veterinary School of Lyons: 4000 francs to François Maignon, for the continuation of his researches on organozymotherapy and for a study of the physico-chemical constitution of the diastases and the mechanism of their action; 4000 francs to Joseph Basset, for the purchase and feeding of experimental animals required for testing two new methods of producing immunity; 2000 francs to G. Marotel, to allow him to continue his researches on the treatment of mange in the dog by a new method.

(6) National Veterinary School of Toulouse: 2500 francs to Charles Besnoit for an experimental study of the methods of intensive application applicable in bovine surgery, and for printing a phototype catalogue for general use; 2000 francs to Jean Lafon, for completing the previous grant of 3000 francs for the purchase of an Einthoven string galvanometer; 1000 francs to Charles Hervieux to enable him to pursue his researches on the transformation in the animal organism of pyrrol groups contained in food, and the elimination of these groups by the urine; 1000 francs to Charles Besnoit and Victor Robin, for a study of the contagious diseases of poultry in the S.W. region.

Independent Grants.—1000 francs to Julien Achard, for completing his monograph on the Madagascan coleoptera of the family of Scaphideideæ; 6000 francs to the Association amicale des élèves de l'École nationale supérieure des Mines for a study of the methods and apparatus for the control of combustion, especially as regards the estimation of carbon dioxide in flue gases; 5000 francs to the École supérieure de perfectionnement industriel as a contribution to the expenses of this institution; 2000 francs to Wilfred Kilian to assist the publication of a geological bibliography of the south-east of France; 5000 francs to Emmanuel de Margerie, for the preparation of the publication of a tectonic map of Eurasia; 15,000 francs to Jean Mascart, for the publication of a part of the astronomical work of Luizet; 3000 francs to M. Mugnier-Serand for his researches on atmospherics in wireless telegraphy and their application to the prediction of storms; 15,000 francs to the Academy of Sciences for the publication of the catalogue of scientific periodicals in Paris libraries.

University and Educational Intelligence.

BIRMINGHAM.—The twenty-third yearly meeting of the Court of Governors is to be held on February 8, and a summary of the events of the past academic year will be presented in the reports of the council and principal (Mr. C. Grant Robertson). The number of students during the past session showed a slight falling off, and the proportion of women increased, except in the Faculty of Medicine, in which it was lower than it had been for some years. It is hoped to repeat, during the present session, the post-graduate course on "The Medical Aspect of Crime and Punishment," for qualified practitioners, which was given last year by Drs. Maurice Nicolls (lecturer in psychotherapy), Hamblin Smith, W. A. Potts, and Percy T. Hughes. Sir Frederick Mott has been appointed, for three years, lecturer in morbid psychology. A Board of Research in Mental Diseases, on which the University and the Asylums Committee of the City Council are represented, has been formed. Sir Frederick Mott is honorary director of research, and the funds are being supplied by the Asylums Committee of the City Council. The most urgent need of the University at present is the removal of the biological group of sciences to new buildings at Edgbaston. This would set free room at Mason College which is urgently required for the Faculties of Arts and Medicine. Reference is made to the successful work of the Workers' Educational Association, and the importance of the co-operation of the University in that work:—"It is essential that the educational work should be controlled by the Universities, if only to secure the right standard . . ., and the need of additional qualified University instructors . . . is already apparent."

Mr. A. W. Nash has been appointed senior lecturer in petroleum technology under Prof. R. R. Thompson. Mr. Nash has had experience in petroleum production and refining in Persia, Russia, and other parts of the world.

CAMBRIDGE.—Sir Alfred Yarrow has offered money for a three-year studentship in Assyriology to provide for the training of a suitable student in a subject which has for the time vanished from the University. He and Lady Yarrow further offer, "if the student prove himself a competent scholar and is prepared to continue the study of Assyriology," to establish with a stipend of 500*l.* a year an "Eric Yarrow lectureship for the study of Assyriology" in memory of Sir Alfred's son, who fell in the war.

A new University lectureship in Psychopathology is advertised as vacant.

Prof. Zschokke, head of the faculty of zoology in the University of Basle, will lecture this term on the European fauna.

The governing body of Emmanuel College offers to a research student commencing residence at the

College in October 1923, a studentship of the annual value of 150*l.*, which shall be tenable for two years and renewable, but only in exceptional circumstances, for a third year. The studentship will be awarded at the beginning of October, and applications should be sent so as to reach the Master of Emmanuel, The Master's Lodge, Emmanuel College, not later than September 18.

LONDON.—The Senate has resolved to increase the annual grant to the Marine Biological Association, Plymouth, from 25*l.* to 50*l.* for the next five years.

The following doctorates have been conferred:—*D.Sc. in Embryology*: Mr. G. S. Sansom, an internal student, of University College, for a thesis entitled "Early Development and Placentation in *Arvicola* (*Microtus*) *amphibius*, with special reference to the Origin of Placental Giant Cells." *D.Sc. in Physiology*: Dr. G. V. Anrep, an internal student, of University College, for a thesis entitled "The Metabolism of the Submaxillary Gland."

Dr. Eustace E. Turner has been appointed demonstrator in the chemical department of the East London College.

ST. ANDREWS.—Principal J. C. Irvine, Dr. William Low, and Dr. Angus MacGillivray have been appointed representatives of the court of the University on a standing joint-committee constituted by the court and the directors of the Dundee Royal Infirmary for the purpose of recommending suitable candidates on the occurrence of vacancies in the chairs of clinical medicine in the University, and also of harmonising the activities of the University and the Infirmary in matters common to both. Prof. D'Arcy Thompson has been reappointed representative of the court on the council of the Scottish Marine Biological Association.

MAJOR-GEN. SIR GERALD ELLISON will unveil the war memorial of East London College on Wednesday, February 7, at 3 P.M.

A SWEDISH professor of education, contrasting Swedish and American schools, remarked that in his own country the word "teacher" is not a noun feminine as it is in America. That the criticism is not without some foundation is shown by the statistics published in Bulletin, 1922, No. 8, of the United States Bureau of Education. The number of men students enrolled in normal courses in all normal schools and teachers' colleges in 1919–20 was 19,110 out of a total of 135,418, or 14 per cent; in teachers' colleges the percentage was 18, in state normal schools 13, in city and county normal schools 6, and in private normal schools 9. Comparative tables of statistics of the five years 1899–1900, 1904–5, 1909–10, 1914–15, and 1919–20 give the numbers of women students in normal courses as 45,394, 49,346, 68,815, 80,347, 116,308, representing the following percentages of the total numbers of students in such courses: 65, 76, 78, 80, 86. The teachers' colleges referred to, 46 in number, are institutions having a four-year course above the secondary school and granting a degree. Of the total number of men students in normal courses (19,110), more than half (9763) were enrolled in these colleges. It is true that a very large proportion of the teachers in American schools have not passed through normal schools and that the percentage of men teachers is not necessarily the same as the percentage of men students in teacher-training institutions. Statistics of City School Systems 1919–20 (Bulletin, 1922, No. 17), however, tell a similar tale. They show that the percentage of men teachers in city schools (including schools in towns having a population of 2500 or more) is 11, while in city elementary schools the percentage is only 4. It is probably safe to assume that rural schools would show an even lower percentage.

Societies and Academies.

LONDON.

Royal Society, January 25.—Sir Charles Sherrington, president, in the chair.—A. V. **Hill**: The potential difference occurring in a Donnan equilibrium and the theory of colloidal behaviour. Loeb has shown experimentally that there is a potential difference between a colloidal solution of a protein and a crystalloid solution with which it is in equilibrium across a membrane, impermeable to the protein, but permeable to the other bodies involved. It varies in the same general manner as the osmotic pressure, the viscosity and the swelling. The variation can be deduced, in general, from the theory of the Donnan equilibrium. One of the chief arguments employed by Loeb, however, is incorrect. Loeb shows that the potential difference observed experimentally agrees very exactly with that "calculated" from the difference in hydrogen ion concentration, also observed experimentally. This is a necessary consequence of the manner in which the observations were made.—E. F. **Armstrong** and T. P. **Hilditch**: A study of catalytic actions at solid surfaces. X.: The interaction of carbon monoxide and hydrogen as conditioned by nickel at relatively low temperatures. A practical synthesis of methane. A mixture of equal volumes of carbon monoxide and hydrogen passed over nickel at temperatures 220-280° C. was largely transformed into methane and carbon dioxide:

$$2CO + 2H_2 = CO_2 + CH_4.$$

This action affords the simplest and most economical means of producing methane in quantity, since a suitable gas mixture exists in ordinary commercial water-gas when the latter has been freed from catalyst poisons by removal of sulphur compounds. The experimental data obtained are compatible with a combination of the "water-gas reaction" with the normal hydrogenation process. Thus, of two volumes of water-gas ($2CO + 2H_2$), one molecule of carbon monoxide and a molecule of water interact and yield a molecule each of carbon dioxide and of hydrogen, the latter, with the balance of hydrogen present in the original gas, furnishing sufficient hydrogen for the normal hydrogenation of a second molecule of carbon monoxide.—J. **Holker**: The periodic opacity of certain colloids in progressively increasing concentrations of electrolytes. The method of testing the effect of common salt on the typical emulsoid colloid, serum, was described. Into each test-tube was pipetted 0·5 c.c. of undiluted serum and to each was then added 2 c.c. of solution of sodium chloride, which progressively increased in concentration in each successive tube. The tubes were shaken and placed in a thermostat at 40° C. for four hours. Then the opacity of the solution was determined. The phenomenon is periodic and is given by colloids of both the emulsoid and suspensoid type, and by animal, vegetable, and mineral colloids. It is also given by certain mixtures of simple aqueous solutions of inorganic salts. Emulsoid colloids tend to give many oscillations of low amplitude. Suspensoid colloids tend to give few oscillations of high amplitude. The phenomenon is not an optical interference of the light scattered by colloidal particles, but is a definite oscillatory change in the physical condition of those particles.—E. K. **Rideal** and R. G. W. **Norrish**: The photochemistry of potassium permanganate. Pt. I: The application of the potentiometer to the study of photochemical change. Pt. II.: On the energetics of the photodecomposition of potassium permanganate. The electrode potential of potassium permanganate when illuminated with ultra-violet light from the mercury vapour lamp undergoes a change (*ca* 0·25 volt) and

recovers slowly in the dark. This change is correlated with a photochemical decomposition of the permanganate, made apparent by the separation of a precipitate of the composition $K_2O \cdot 2MnO_2$, and the formation of a sol of MnO_2. Illumination establishes a photochemical stationary state, KOH being simultaneously produced by the decomposition, and removed by combination with the colloidal MnO_2. This involves an alteration of the P_H of the solution, which causes the electrode potential changes. The decomposition is monomolecular over the range of concentrations investigated. The decomposition of acidified permanganate under identical conditions is of zero order, due to non-formation of colloid. The photoactive radiation lies in the ultra-violet absorption spectrum of potassium permanganate, and the Hg line at 3128 Å.U. is considered the chief agent. The quantitative absorption of radiant energy is in agreement with the Einstein Law of Photochemical Equivalent, a result of special interest as the first instance of its application to solutions.—E. A. **Fisher**: Some moisture relations of colloids. Pt. I.: A comparative study of the rates of evaporation of water from wool, sand and clay. Curves obtained by plotting rates of evaporation against water contents are discontinuous. Each portion of the rate curve can be expressed by a simple type of equation connecting rate of evaporation with water content. The rate curves obtained are similar in type in the cases of wool (wholly colloidal with a cellular structure), quartz sand (wholly non-colloidal with a granular structure), silty soil (notoriously feeble in colloid properties), and heavy clay sub-soil (typically colloidal in behaviour). The so-called shrinkage of wool on drying is really a deformation and not a volume shrinkage. The absorption of water by wool is attributed primarily to a filling up of fine pores of various shapes and sizes; the vapour pressures of wool-water systems are determined by the diameters of the pores that are full of water.—R. **Whytlaw-Gray**, J. B. **Speakman** and J. H. P. **Campbell**: Smokes. Pt. I.: A study of their behaviour and a method of determining the number of particles they contain. The smokes were produced (*a*) by the arc discharge in air, (*b*) by volatilisation and condensation, (*c*) by chemical action. In each case highly dispersed systems of very minute particles were obtained. Examined in an ultra-microscope of the slit type, the life-history of a smoke falls into two main periods:—(*a*) An unstable period in which the number of particles diminishes rapidly with time. (*b*) A stable period in which the decrease in number is slow. During the first period the increase in size is very marked; the changes are not due to evaporation but to a process of aggregation, which produces complexes of different structure depending on the nature of the dispersed substance.—R. **Whytlaw-Gray** and J. B. **Speakman**: Smokes. Pt. II.: A method of determining the size of the particles they contain. A filtration method is used which enables the concentration in weight of the suspended solid matter in rapidly changing smokes to be determined with an accuracy of about 3 per cent. A given volume of smoke (usually 1 litre) is filtered through small tubes containing asbestos, and the increase in weight is ascertained by a micro-balance sensitive to 0·0002 mgm. Filtration takes about five minutes. Curves have been obtained showing the variation in weight concentration of the smoke over periods of 0-6 hours. Knowing the weight and the number of the particles in a given volume, the average mass of a smoke particle at different periods can be calculated and the growth followed quantitatively. Assuming the density of the particle to be that of the substance in bulk the average radius can be evaluated. All the weight-concentration curves show an initial rise, and this fact, in conjunction with ultra-microscopic observations, renders it probable that all these clouds contain in the early stages a large number of invisible particles of a microscopic size.—R. C. **Ray**: The effect of long grinding on quartz (silver sand). When quartz (silver sand) is ground for a long time the density of the ground substance is lower than the one which has not been subjected to grinding. The fall of density shows that as much as 25·7 per cent. of the material is converted from the crystalline to the vitreous condition. This value agrees fairly with that derived from the molecular heats of solution.

Geological Society, January 10.—Prof. E. J. Garwood, vice-president, and afterwards, Prof. A. C. Seward, president, in the chair.—W. J. **Sollas**: Man and the ice-age. Four ancient coast-lines of remarkably constant height have been traced around the Mediterranean Sea and along the western shores of the North Atlantic Ocean. These, with their associated sedimentary deposits, form the successive stages of the Quaternary system; namely, the Sicilian (coast-line about 100 metres); the Milazzian (coast-line about 60 m.); the Tyrrhenian (coast-line about 30 m.); and the Monastirian (coast-line about 20 m.) The Sicilian deposits contain a characteristic cold fauna. The fauna of the Milazzian is warm-temperate and of the Tyrrhenian and Monastirian still warmer. The three lower coast-lines correspond with the three lower river-terraces of the Isser (Algeria), the Rhône, and the Somme. Hence it may be inferred that the position of the river-terraces has been determined by the height of the sea-level. The climate of the Quaternary age was, on the whole, warm-temperate or genial, but interrupted by comparatively short glacial intervals. It is now possible to assign the palæolithic stages of human industry to their place in the Quaternary system: thus the "Strepyan" or pre-Chellean is Milazzian in age, the typical Chellean, Tyrrhenian, the evolved Chellean, Acheulean, and Lower Mousterian, early Monastirian, and the Upper Mousterian, Aurignacian, Solutrian, and Magdalenian, later Monastirian. The coast-lines of the Northern Hemisphere appear to have their counterparts in the Southern Hemisphere. The Quaternary movements are probably due to a general deformation of the globe involving eustatic changes in the level of the sea.

Optical Society, January 11.—C. **Davidson**: On the amount of the displacement in gelatine films shown by precise measurements of stellar photographs. A stellar photograph consists of a number of minute discs scattered over an otherwise transparent plate. The purpose of the photograph is to determine with precision the relative positions of these discs. In the trigonometrical method of determining stellar parallaxes photographs of a selected region are taken at two epochs about six months apart when the earth is at opposite sides of its orbit. A new star will show a displacement relatively to the distant stellar background. A series of such photographs give equations from which the parallax and proper motion are determined. After the computed quantities have been taken out, each plate will show a small residual error made up of errors of measurement, observing, etc., and film displacement. From a discussion of many plates from Greenwich it appears that the average probable error of the measured position of a star on a single plate is ±0·0008 mm. Film displacement being only a part of the total it follows that this must be the upper limit of the probable error of film displacement. In the Kapteyn system of observation, the photographs at the two epochs are taken on

the same plate, which is stored away during the interval and developed after the second exposure. It was arranged that the images fell near each other (within 1 mm.—they were, however, too small for the Ross effect to come into action) and only the small differences separating the images were measured, any film displacement which would affect both images equally, consequently disappearing. This method has now been given up in favour of single plates, but a number of the Kapteyn pairs have since been measured treating each photograph as a separate plate. From a discussion of the residuals of some 300 plates the film error is ±0·0003 mm.

The Faraday Society, January 15.—Sir Robert Robertson, president, in the chair.—E. W. J. **Mardles**: Study of the reversible sol to get transition in non-liqueous systems. Pt. 1: The change of viscosity with time during gelation. The viscosity value of a sol during its gelation is dependent on the method and conditions of its determination, and since the system is heterogeneous, it loses its real significance. The change of apparent viscosity with time during the gelation of a sol of cellulose acetate in benzyl alcohol can be expressed by an empirical formula. The temperature, when the rate of gelation becomes nil, is regarded as the maximum gelation temperature, since above it the sol is relatively stable with time and below it a part or whole of the dispersed particles aggregate to form a gel structure. The relation between the maximum gelation temperature and concentration resembles that between temperature and the saturation concentration for crystalloids. Pt. 2: Viscosity changes associated with the gel to sol transition. These have been measured at various temperatures and with different concentration systems of cellulose acetate in benzyl alcohol. The viscosity at first rapidly diminishes, the rate of change becoming smaller until a constant value is obtained. The minimum temperature at which there is a complete return to the original viscosity of the sol without mechanical treatment is termed the minimum solation temperature. Mechanical treatment hastens solation in the same way that it retards gelation. The time taken for a system to attain constant viscosity or mobility depends on the previous treatment of the gel. The hysteresis effect observed during the sol⇌gel transition can be measured by the difference in the temperature of minimum solation from that of maximum gelation, and the cause of it has been ascribed to the different conditions of the particles in the gel and sol state.—E. W. J. **Mardles**: Changes of volume and refractive index associated with (*a*) the formation of organosols and gels; (*b*) the reversible sol to gel transition. In general, the volume changes are largest (*a*) at the lower concentrations, (*b*) with the best solvents and optimum solvent mixtures, and (*c*) at higher temperatures. They are much smaller than those observed by other workers for hydrosols and gels. The reversible sol to gel transition is associated with a small volume change which varies with time as in the case of the Tyndall number changes. There are also indications of a change of refractive index corresponding to the volume and Tyndall number changes during the reversible sol to gel transition.—E. W. J. **Mardles**: The scattering of light by organo-sols and gels of cellulose acetate. Measurements of the change with temperature of the Tyndall number of sols and gels of cellulose acetate in benzyl alcohol during the reversible sol to gel transition show that with fall in temperature of the sol the rate of change is small until a certain critical temperature, after which it increases with acceleration. Eventually there may be a point of inflexion on the curve, the position of which depends on the rate of cooling, and is determined by the formation of a firm jelly structure which inhibits the development of opalescence. The Tyndall number of a gel is a function of the mechanical treatment as well as rate of gelation and it varies with time, the rate of change rapidly diminishing in absence of mechanical treatment. A gel tends to increase its Tyndall number, and mechanical treatment may induce opalescence. The Tyndall number-concentration curve contains a maximum which tends to disappear at higher temperatures, thus the size of the particles in a gel structure is a function of the concentration and the temperature at which it was formed. The curve resembles Tammann's curve relating the number of crystallisation nuclei, or rate of crystallisation, with the degree of supersaturation.—J. R. **Partington** and W. J. **Shilling**: The variation of the specific heat of air with temperature. The velocity of sound in the gas contained in a large silica tube arranged as an electrically heated furnace was measured at intervals of approximately 100° C., from room temperature up to 1000° C. The values obtained up to 700° C. lie practically on the line given by $C_v = 4{\cdot}849 + 0{\cdot}000358T$ grm. cal. Above 700° C_v appears to increase more rapidly with temperature, but at present the values above 800° are uncertain.

Royal Anthropological Institute, January 16.—Dr. F. C. Shrubsall, treasurer, in the chair.—Mr. M. **Addison**: Human heads carved in steatite from Sierra Leone. The Mende tribes, in whose territory the heads were obtained, know nothing of their origin, but although the heads exhibit certain characteristics, such as nose- and ear-rings and long drooping moustaches, which do not occur among the inhabitants of the district at the present day, it is not probable that they are of a very high antiquity, their age possibly being two or three hundred years. Among the Mende the heads are used for magical purposes, and, placed on mounds in the fields, are thought to increase the fertility of the crops.—F. W. H. **Migeod**: The Bedde group of tribes of Northern Nigeria. Though extending from Lake Chad as far as the City-State of Hadeija the Bedde are not a well-known people. They have the legend that they originated in Yemen in Arabia and that they were the first people driven out of Arabia in consequence of their refusal to accept Mohammedanism. The Western-most branch of the Bedde, the Awuyoka, have a list of kings going back to the 12th century. The language shows no traces of an Arabian origin. The Bedde live in round huts grouped in compounds, and formerly all the towns were surrounded by a rectangular mud embankment, but most of the defensive works are now in ruins. Swords, spears, and bows and arrows are the offensive weapons. Children are named by the father, but there are fixed names for twins, male and female. Marriage may take place into any family. Corpses are buried on the right side with head to the south and so facing east, the hands being drawn down and placed together. The Bedde seem to be very superstitious and to believe in omens. They are divided up into animal tribes such as Leopard, Hippopotamus, etc., which form a bond outside family life. No worship is offered to the tutelary animal, but it must not be killed or eaten by those who bear its name. The people now nearly all wear gowns of cotton like the Hausas or Bornuese. They slash or cut their faces with a main design and subsidiary marks. The men shave their heads but the women indulge in fancy head-dressing. They are not a short race. They usually have broad faces, some being very broad across the cheek-bones, and usually have heads low above the ears and receding foreheads; but there is great variety.

Royal Microscopical Society, January 17.—Prof. F. J. **Cheshire**: The early history of the polariscope and the polarising microscope (presidential address). The early history of double refraction, from 1669, when Bartholinus first received specimens of spar from the Bay of Roërford in Iceland, up to 1808, when Malus, by a happy chance, made the wonderful discovery of polarisation by reflection, and the identity of the light thus produced with the refracted beams given by Iceland Spar, was discussed. The difficulty was considered of explaining double-refraction on Huygens' undulatory theory, disposed of by Fresnel in 1821, who abandoned the theory of longitudinal vibrations, and substituted transverse ones for them, after having proved, with Arago in 1816, that oppositely polarised beams do not interfere in the same way that Young had shown beams of ordinary light do. The work of Brewster and Biot was referred to, and some account given of the extraordinary amount of work done between Malus's discovery in 1808, and the invention of the Nicol prism in 1828, from which date the modern microscope dates. In the early days the polarising microscope was employed primarily for the examination of general objects, whereas the application of the petrological microscope to the systematic study of rock-sections dates no further back than 1870. Various forms of polariscopes, including a remarkable one invented by Airy in 1831, were described, and possibilities of further improvements discussed. It was urged that the work of Herapath and others in the production of artificial tourmalines should be again taken up. Finally, to meet the present difficulties of supplying students' microscopes it was urged that teachers and manufacturers should come to an agreement as to the simplest possible designs with which the students' work could be done.

PARIS.

Academy of Sciences, January 8.—M. Albin Haller in the chair.—A. **Haller** and R. **Lucas**: Study of the absorption in the ultra-violet of a series of derivatives of camphor. Certain derivatives of camphor of the type $C_8H_{14}\begin{matrix}C=CH\cdot R\\ CO\end{matrix}$ show anomalies in their optical properties (dispersion, molecular refraction, rotatory power) compared with the corresponding reduction products. Seven substances of the first type and two of the second have been studied from the point of view of their ultra-violet absorption spectra, and the results given in the form of the curves suggested by Lord Rayleigh.—P. A. **Dangeard** and Pierre **Dangeard**: The vitality of Aucuba leaves preserved in a vacuum. An adult leaf of Aucuba placed in a vacuum and exposed to light during six months preserved all its cells alive, and no important difference could be detected between the structure of these cells and that of the leaves remaining on the tree.—Th. **Anghelutza**: The representation of functions of one real variable.—Gaston **Julia**: Rational substitutions with two variables.—J. F. **Ritt**: Rational permutable functions.—G. V. **Pfeiffer**: A special method of integration of partial differential equations of the first order.—Torsten **Carleman**: The effective calculation of a quasi-analytical function, the differentials at a point being given.—Emile **Borel**: Remarks on the preceding note of M. Torsten Carleman.—Paul **Dienes**: Transfinite series of real numbers.—Tadé **Wazewski**: Measurable *ensembles*.—G. **Bratu**: Curves defined by recurrent series.—J. **Chuard**: Some properties of cubical networks traced on a sphere.—David **Wolkowitsch**: The infinitely small movements at a point of an elastic body admitting a plane of symmetry. Charles **Frémont**: The influence of the velocity of impact in the calibration of dynamometer springs. The experiments were arranged with falling weights so chosen that the product of the weight by the height fallen remained constant. The deflections of the spiral spring increased as the velocity of impact diminished: the anomalous result is due to the inertia of the spring.—J. **Guillaume**: Observations of the sun made at the Observatory of Lyons during the third quarter of 1922.—R. **Lucas**: Natural and magnetic rotatory power. If a substance possessing natural optical activity is suitably placed in a magnetic field, the substance acquires a complex rotatory power. The question as to whether there is simple additivity of the two rotatory powers, or whether the two phenomena exert a mutual influence on each other is investigated mathematically, and the conclusion is arrived at that the change in the natural rotatory power produced by the action of the magnetic field would be too small to put in evidence experimentally.—A. **Catalán**: The structure of the arc spectra of the elements of columns VI and VII of the periodic table.—G. **Reboul** and P. **Blet**: The different aspects of the electrical discharge in crystals.—A. **Grumbach**: Batteries with fluorescent liquid. If two platinum electrodes dip into a fluorescent solution and one of them is illuminated, an electromotive force is produced which varies with time. Some experimental results with solutions of uranine in water are given proving that Goldmann's explanation of the phenomenon is inadequate.—A. **Bigot**: The action of heat on kaolins, clays, etc. Ceramic plastic materials, under the action of heat, harden without dehydration and without change of volume. The colloidal plasticity is reduced by this heating.—Roger G. **Boussu**: A method for studying the velocity of formation of precipitates.—F. **Bourion**: The normal acids of Berthelot and the theory of ions.—Henri **Bénard** and Albert **Laborde**: The estimation of albumen by nephelemetric methods.—Mlle. S. **Veil**: The evolution of the molecule of ferric-hydroxide in water: the dehydration of ferric-hydroxide by ignition or by heating with water in sealed tubes to temperatures between 120° C. and 210° C. has been co-ordinated with the changes produced in the magnetisation coefficient.—B. **Bogitch**: The removal of sulphur from metals by lime. A study of the decomposition by lime, in the presence of carbon, of some metallic sulphides dissolved in the fused metal. Copper, nickel, iron, and manganese were studied, the action of lime and basic slag being examined separately. A mixture of lime and fluorspar gave the best results.—Mlle. de la **Paulle**: The estimation of potash as alum.—R. **Douris** and G. **Beytout**: The mercuric compounds of hexamethylenetetramine.—Carl **Störmer**: Results of the photogrammetric measurements of the aurora borealis of March 22-23, 1920. The greatest altitude measured was 750 kilometres; in no case was the height less than 100 kilometres.—Octave **Mengel**: New seismotectonic views, resulting from the earthquakes felt between August and December 1922, in the eastern part of the Pyrenees.—M. **Stefanescu**: The growth in two opposite directions, and the marks of friction and pressure, of the molars of mastodons and elephants.—L. **Joleaud**: Sub-fossil hippopotami of Madagascar and the recent geographical connexions of this island with the African continent.—Albert **Baldit**: The undulatory movements of the atmosphere and their utilisation in aviation without a motor.—Jean **Mascart**: The quantity of heat received by the earth in the course of the seasons.—F. **Diénert**: Considerations on the formation of springs.—J. **Cluzet** and A. **Chevallier**: The use of thorium emanation in inhalation. By utilising radiothorium from the sludge

derived from the Echaillon springs, thorium emanation has been used directly by inhalation, and the therapeutic results obtained proved to be comparable with those given by other methods of treatment.—Jean **Bathellier**: The fungus gardens of *Entermes Matangensis*. These ants cultivate fungi (identified as a Xylaria) in special chambers.—G. **Marinesco**: Oxidising ferments and thermogenesis.—F. **Vlés**, J. **Dragoin**, and M. **Rose**: Researches on the hydrogen-ion concentration arrest of egg division in the sea urchin.—L. J. **Simon** and L. **Zivy**: The mixture of tartrates and phosphates regarded as buffer substances. The antagonistic action of calcium chloride.—Emile **Misk**: Tin in the human organism. Reference is made to the frequent presence of traces of tin in preserved foods. Tin appears to be present in the human body, the largest proportion being found in the liver. From the physiological point of view it is interesting to note that the body appears to contain normally at least as much tin as zinc.—Boris **Ephrussi**: The spermatogenesis of *Balanus perforatus*.—A. **Trillat**: The different properties of dry or liquid bacterial dusts.—C. **Levaditi** and S. **Nicolau**: Inoculation of the herpetic virus in the genital organs of the rabbit. Transmission of the herpeto-encephalitic infection by sexual contact.

Official Publications Received.

Memoirs of the Asiatic Society of Bengal. Vol. 8, No. 1: Ismailitica. By W. Ivanow. Pp. 76. (Calcutta: Asiatic Society of Bengal.) 2 rupees; 3s.

City and County of Bristol: The Bristol Museum and Art Gallery. Report of the Museum and Art Gallery Committee for the Year ending 30th September 1922. Pp. 23. (Bristol.)

Diary of Societies.

MONDAY, FEBRUARY 5.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Meeting.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. H. E. Griffiths: The Relation of Diseases of the Gall Bladder to the Secretory Function of the Stomach and Pancreas.

SOCIETY OF ENGINEERS, INC. (at Geological Society), at 5.30.—A. Collis-Brown: Practical Notes on Inspection.

INSTITUTE OF TRANSPORT (at Institution of Electrical Engineers), at 5.30.—H. N. Gresley: Wagon Stock on British Railways.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—J. Coxon and others: Discussion, The Supply of Steady D.C. for Telephonic and other Purposes.

ARISTOTELIAN SOCIETY (at University of London Club), at 8.—Miss May Sinclair: Primary and Secondary Consciousness.

ROYAL SOCIETY OF ARTS, at 8.—Dr. H. P. Stevens: The Vulcanisation of Rubber (Cantor Lectures) (1).

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Engineers' Club, Coventry Street), at 8.—G. T. Bray and F. Major: The Estimation of Fat in Casein.—Dr. E. Fyleman: Explosions in Liquid Air Rectification Plant.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.30.—Presidential Address to Students and Presentation of Prizes.

TUESDAY, FEBRUARY 6.

AIR CONFERENCE (at the Guildhall, E.C.), at 10.30.—Maj.-Gen. Sir W. J. Brancker: The Position of Air Transport To-day.—Comdr. C. D. Burney: A Self-supporting Airship Service. At 2.45.—Air Vice-Marshal Sir W. G. H. Salmond: The Progress of Research and Experiment.—Col. A. Ogilvie: Gliders and their Value to Aeronautical Progress.—C. R. Fairey: Seaplanes.

INSTITUTION OF HEATING AND VENTILATING ENGINEERS (Annual General Meeting) (at the Holborn Restaurant), at 2.30.—Prof. W. E. Garner: Theory of Combustion of Gaseous and Liquid Fuels.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—R. D. Oldham: The Character and Cause of Earthquakes (2).

ROYAL SOCIETY OF ARTS (Dominions and Colonies and Indian Sections), at 4.30.—Sir Richard A. S. Redmayne: The Base Metal Resources of the British Empire.

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—The Secretary: Report on the Additions made to the Society's Menagerie during the months of November and December 1922.—E. G. Boulenger: Account of Experiments on Amphibians and Insects at Vienna.—C. A. A. Dighton: Coat-colour in Greyhounds.—E. L. Gill: The Permian Fishes of the Genus Acentrophorus.—Dr. C. F. Sonntag: The Vagus and Sympathetic Nerves of the Terrestrial Carnivora.—E. P. Allis, Jr.: The Postorbital Articulation of the Palato-quadrate with the Neurocranium in the Cœlacanthidæ.—Dr. G. S. Giglioli: The Linguatulid Arachnid, *Raillietiella furcocerca* (Diesing, 1835), Sambon, 1922.—Rita Markbreiter: Some *Microfilaria* found in the Blood of Birds dying in the Zoological Gardens, 1920–1922.

INSTITUTION OF CIVIL ENGINEERS, at 6.—D. H. Remfry: Wind-Pressures, and Stresses caused by the Wind on Bridges.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—Major O. Rutter: The Natives of North Borneo.

RÖNTGEN SOCIETY (at Institution of Electrical Engineers), at 8.15.

WEDNESDAY, FEBRUARY 7.

AIR CONFERENCE (at the Guildhall, E.C.), at 10.30.—General Discussion on the Papers read in the morning of February 6. At 2.45, General Discussion on the Papers read in the afternoon of February 6.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. G. Keynes: Chronic Mastitis.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—G. V. Douglas: The Geological Results of the Shackleton-Rowett (*Quest*) Expedition.

NEWCOMEN SOCIETY (at Alpine Club), at 5.30.—G. P. Baker: East Indian Cotton Prints and Paintings of the 17th and 18th Centuries.

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—J. Hollingworth: The Measurement of the Electric Intensity of Received Radio Signals.

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (Annual General Meeting) (at Chemical Society), at 8.—Presidential Address.—O. Jones: Notes on the Examination of Preserved Meats, etc.—E. Griffiths-Jones: Titanium in Nile Silt.

ROYAL SOCIETY OF ARTS, at 8.—C. R. Darling: Electrical Resistance Furnaces and their Uses.

FELLOWSHIP OF MEDICINE (at Royal Society of Medicine), at 8.30.—J. P. Lockhart-Mummery: Diverticulitis.

THURSDAY, FEBRUARY 8.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. I. M. Heilbron: The Photosynthesis of Plant Products (2).

ROYAL SOCIETY, at 4.30.—Prof. L. Bairstow, Miss M. B. Cave, and Miss E. D. Lang: The Resistance of a Cylinder moving in a Viscous Fluid.—G. I. Taylor: The Motion of Ellipsoidal Particles in a Viscous Fluid.—L. F. Richardson: Theory of the Measurement of Wind by Shooting Spheres Upward.—Prof. W. E. Palby: Further Researches on the Strength of Materials.—L. C. Jackson and Prof. H. Kamerlingh Onnes: Investigations on the Paramagnetic Sulphates at Low Temperatures.—L. C. Jackson and Prof. H. Kamerlingh Onnes: Investigations on the Paramagnetism of Crystals at Low Temperatures.—Prof. E. Wilson: The Susceptibility of Feebly Magnetic Bodies as affected by Tension.—W. D. Womersley: The Specific Heats of Air, Steam, and Carbon Dioxide.

WOMEN'S ENGINEERING SOCIETY (26 George Street, W.1.), at 6.15.—E. W. C. Kearney: The Kearney High-speed Railway.

OPTICAL SOCIETY (Annual General Meeting) (at Imperial College of Science and Technology), at 7.30.—Sir Frank Dyson: Large Telescopes (Presidential Address).—Discussion on paper by F. W. Preston: The Properties of Pitch used in Working Optical Glass. A new *prismatic astrolabe* designed at the Admiralty Research Laboratory exhibited and described by Commdr. T. Y. Baker.

CAMERA CLUB, at 8.15.—C. H. L. Emanuel: Notes of a Collector of Prints and Drawings.

INSTITUTE OF METALS (London Local Section) (at Institute of Marine Engineers, Inc.), at 8.30.—Miss M. L. V. Gayler: The Investigation of the Constitution of Alloys.

FRIDAY, FEBRUARY 9.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Anniversary.

PHYSICAL SOCIETY OF LONDON (Annual General Meeting) (at Imperial College of Science and Technology), at 5.—Sir William Bragg: The Crystalline Structure of Anthracene.—Capt. H. Shaw and E. Lancaster-Jones: The Eötvös Torsion Balance.—H. W. Heath: Demonstration of the Flame Phone.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. L. R. Rawling: Remote Effects of Gun hot Wounds of the Head.

MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Adjourned Discussion on Symposium of Papers on Indicators:—L. Pendred: The Problems of the Engine Indicator.—Prof. F. W. Burstall: A New Form of Optical Indicator.—W. G. Collins: Micro-Indicator for High-Speed Engines.—H. Wood: R.A.E. Electrical Indicator for High-Speed Internal-Combustion Engines, and Gauge for Maximum Pressures.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—Prof. F. C. Lea: The Effect of Temperature on the Properties of Engineering Materials.

PHILOLOGICAL SOCIETY (at University College), at 8.—J. Hodgkin: Macaronic Poetry.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Sir John Russell: "Rothamsted" and Agricultural Science.

PUBLIC LECTURES.

SATURDAY, FEBRUARY 3.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—F. Balfour-Browne: Insect Pests and their Control.

MONDAY, FEBRUARY 5.

KING'S COLLEGE, at 5.—N. B. Jopson: The Original Home of the Slavs.

UNIVERSITY COLLEGE, at 5.—Sir John Russell, and staff of the Rothamsted Experimental Station: The Micro-Organic Population of the Soil (succeeding Lectures on February 7, 12, 14, 19, 21, 27, March 1, 5, and 7).

TUESDAY, FEBRUARY 6.

GRESHAM COLLEGE, at 6.—W. H. Wagstaff: Geometry (succeeding Lectures on February 7, 8, and 9).

WEDNESDAY, FEBRUARY 7.

KING'S COLLEGE, at 5.30.—Dr. J. S. Haldane: The Fundamental Conceptions of Biology.

THURSDAY, FEBRUARY 8.

UNIVERSITY COLLEGE, at 5.30.—G. A. Sutherland: The Acoustics of the Auditorium. (Succeeding Lectures on February 15 and 22.)

CENTRAL LIBRARY (Fulham), at 8.—Mrs. G. Skelton: Women and Industry.

FRIDAY, FEBRUARY 9.

UNIVERSITY COLLEGE, at 8.—Miss E. Jeffries Davis: The Evolution of London (succeeding Lectures on February 16 and 23).

SATURDAY, FEBRUARY 10.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—E. Lovett: Household Appliances of a Hundred Years Ago.

NEGRETTI & ZAMBRA
38, HOLBORN VIADUCT, E.C.1.
LONDON.

UNIVERSITY OF LONDON.

A Course of three Lectures in Zoology (with lantern illustrations) on "THE BIONOMICS OF MARINE ANIMALS" will be given by DR. J. H. ORTON, D.Sc. (of the Marine Biological Association, Plymouth), at KING'S COLLEGE, LONDON (Strand, W.C.2), on TUESDAY, February 20, THURSDAY, February 22, and FRIDAY, February 23, 1923, at 5.15 P.M. At the first Lecture the Chair will be taken by Prof. ARTHUR DENDY, F.R.S. (Professor of Zoology in the University). ADMISSION FREE, WITHOUT TICKET.

EDWIN DELLER, Academic Registrar.

GEOLOGICAL SOCIETY OF LONDON.

The ANNIVERSARY MEETING of this Society will be held at the SOCIETY'S APARTMENTS, BURLINGTON HOUSE, on FRIDAY, February 16, at 3 o'clock.

The Fellows and their Friends will dine together at the Café Royal at 7.30 P.M. Tickets 20s. each (inclusive of still wines), to be obtained from the CLERK not later than February 12.

THE MURDOCH TRUST.

For the benefit of INDIGENT BACHELORS and WIDOWERS of Good Character, over 55 years of age, who have done "something" in the way of Promoting or Helping some branch of Science.

Donations or Pensions may be granted to persons who comply with those conditions.

For Particulars apply to Messrs J. and J. TURNBULL, W.S., 58 Frederick Street, Edinburgh.

KEBLE COLLEGE, OXFORD.

NATURAL SCIENCE SCHOLARSHIP, 1923.

An Examination will be held in this College on March 13 for two SCIENCE SCHOLARSHIPS of the annual value of £80, with laboratory fees £20.

Subjects: Chemistry *or* Biology, with elementary Physics, and for Biologists elementary Chemistry as well.

Intending candidates should apply to Dr. HATCHETT JACKSON, the Science Tutor, for information.

RESEARCH FELLOWSHIPS IN ACOUSTICS.

THE RIVERBANK LABORATORIES AT GENEVA, ILLINOIS, announce the establishment of one or two RESEARCH FELLOWSHIPS in ACOUSTICS. The holder will have an opportunity to devote his entire time to study and investigation in a laboratory built, equipped, and manned for the study of acoustic problems. Candidates should be college graduates who have taken advanced courses in physics and mathematics, and who have shown in their work those qualities essential for success in independent investigation. Terms of appointment to be determined by the qualifications of the appointee. Address, B. CUMMING, Secretary, Geneva, Illinois.

THERESA SEESSEL RESEARCH FELLOWSHIP

To promote Original Research in Biological Studies.

YALE UNIVERSITY.

One FELLOWSHIP, yielding an income of $1500. Preference is given to candidates who have already obtained their Doctorate, and have demonstrated by their work fitness to carry on successfully original research of a high order. The holder must reside in New Haven during the college year, October to June. Applications should be made to the DEAN of the GRADUATE SCHOOL, New Haven, Conn., before May 1, 1923; they should be accompanied by reprints of scientific publications, letters of recommendation, and a statement of the particular problem which the candidate expects to investigate.

UNIVERSITY COLLEGE, SOUTHAMPTON.

REGISTRAR.

Applications are invited for the post of REGISTRAR in the above College. The selected candidate will be required to take up his duties on September 1, 1923.

For full particulars apply to the PRINCIPAL.

MUSEUM ASSISTANT; Youth 18, seeks

post. Camb. Senr. 2nd Class Honours, Matric. Exempn., Entomologist, Illustrations line and colour. Natural History. Prehistoric Man, References. K. WILKINSON, 64 Lengstone Road. Eastbourne.

MINISTRY OF EDUCATION FOR NORTHERN IRELAND.

The Ministry of Education for Northern Ireland invite applications for the position of

A SENIOR INSPECTOR.

Candidates must be men holding a good Honours Degree in MATHEMATICS from some Irish or British University. They should not be more than 35 years of age, and must have had some teaching experience. A University Diploma in teaching is also desirable.

The Inspector appointed will be required to inspect classes in Secondary and Technical Schools, and to carry out any other duties which may be assigned to him by the Ministry.

The Salary attached to the position begins at £400 per annum, and increases by annual increments of £20 to £700 per annum, together with the Cost of Living Bonus at Civil Service rates, travelling expenses, and the usual subsistence allowances.

Applications, accompanied by one copy of each of three recent testimonials, should be addressed to the SECRETARY, Ministry of Education for Northern Ireland, Parliament Buildings, Belfast, and must be received not later than FEBRUARY 28, 1923.

Forms of application may be obtained from the Ministry.

UNIVERSITY OF SYDNEY, NEW SOUTH WALES.

PROFESSORSHIP OF PHYSICS.

The Senate of the University of Sydney invites application for the CHAIR of PHYSICS, to which is attached a salary of £1100 per annum together with rights to a pension of £400 per annum on certain conditions. The Professor appointed will be expected to enter on his duties on August 1, 1923; £150 will be allowed for travelling expenses from Europe.

Further details concerning the appointment may be obtained on written request to THE AGENT-GENERAL FOR NEW SOUTH WALES, AUSTRALIA HOUSE, STRAND, LONDON, W.C.2, to whom applications for the position, in sextuplicate, accompanied by copies of testimonials (if any), should be sent so as to reach him not later than Wednesday, FEBRUARY 28, 1923. There is no special form of application. All correspondence addressed to the Agent-General in connection with the appointment should be marked on the outside of the envelope "University of Sydney."

T. A. COGHLAN,
London, January 30, 1923. Agent-General for New South Wales.

UNIVERSITY OF LONDON.

The Senate invite applications for the UNIVERSITY READERSHIP in CULTURAL ANTHROPOLOGY tenable at University College. Salary £600 a year. Applications (12 copies) must be received not later than first post on February 22, 1923, by the ACADEMIC REGISTRAR, University of London, South Kensington, London, S.W.7, from whom further particulars may be obtained.

MINISTRY OF AGRICULTURE AND FISHERIES.

Applications are invited for an appointment as ASSISTANT INSPECTOR in connection with Agricultural and Horticultural Education and Research.

Candidates must be not less than 22 years of age, and in addition to possessing practical experience in Horticulture should have taken a Natural Science Course (including Botany and Zoology) at a British University.

Salary £150 per annum rising to £250 per annum plus Civil Service Bonus.

Preference will be given to ex-service Applicants.

Forms of application and copies of the Regulations affecting these appointments can be obtained from the SECRETARY, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1. Application forms must be returned not later than February 26.

A FIRST-CLASS COLLECTION OF

MINERALOGICAL SPECIMENS FOR SALE IN LONDON (privately collected by the late W. Semmons).

For further particulars write:

AA, 3 Chestnut Avenue, Chorlton cum Hardy, MANCHESTER.

WANTED—For Permanent Post in a Milk-

producing District, Man with experience of Dairy Laboratory Technic. Must possess thorough knowledge of dairy husbandry and production of milk under hygienic conditions. Write, sending full particulars of past experience and knowledge, also stating salary expected, to Box 124, MATHER & CROWTHER Ltd., 10 New Bridge Street, London, E.C.4.

TO CONSULTING AND RESEARCH

CHEMISTS—Fitted Laboratories and Office accommodation to be let. Some apparatus for disposal. Within a few minutes' access of the Bank. Box 53/10, c/o NATURE Office.

WANTED—A Microscope for Laboratory

use. 2/3rd, 1/6th, and 1/12th powers. Write fullest particulars and price to PLAUSON'S, 17 Waterloo Place, S.W.1.

CHEMIST—1st Class Honours, B.Sc., etc.;

works experience; fluent French, German, some Russian, Italian. Post or part-time work. Box 53, c/o NATURE Office.

NO. 2780, VOL. 111]

Science Teaching.

IT has long been felt that a great defect in our secondary school education has been that boys and girls may pass on to the universities or out into the world of business without having received any instruction in science or any skilled guidance in the pursuit of their scientific hobbies. It is owing probably to a defect of this kind in the education of many of our public men that we have so often to complain of the indifference that is shown to pressing necessities for the better encouragement and endowment of scientific research. It is true that many of our large public schools are now provided with first-rate teachers of science and with well-equipped scientific laboratories, so that the boy or girl who takes the modern side may receive a really good foundation of scientific knowledge. It is also true, however, that, owing to the tyranny of our scholarship system the classical boys in the upper forms of secondary schools have not time to devote to instruction in any branch of science, and for the same reason the education of boys in elementary science is too frequently neglected, both in the preparatory schools and in the lower forms of secondary schools.

What is wanted in education is the cultivation of the idea that no modern citizen can be considered really well educated who has not gained some knowledge of the natural phenomena of the world in which he lives, and of the body which is the temple of his soul. If we could persuade all parents of the truth of this conception, they would not be satisfied with the education of their children unless they have had, at least in the preparatory school or in the lower forms of the secondary school, some instruction in science.

There has been some difficulty, however, in coming to an agreement as to the best and most practical form in which science should be taught in the lower forms; and it is, therefore, with great pleasure that we welcome the valuable report, just published, of a sub-committee of the Science Masters' Association.[1] The fundamental principle that underlies the method of education suggested in the report is that "the work should be done by the boys themselves with as little help as possible from the master in charge"; and accordingly, a syllabus is drawn up of subjects which, experience has shown, can be studied effectively and with simple appliances in school life. Included in the report there are also an interesting and valuable syllabus of subjects arranged as a calendar of work, and three specimens of lessons that may be given in natural history.

All this is excellent and worthy of most careful study

[1] Elementary Science, Nature Study, and Practical Work in Preparatory Schools and the Lower Forms of Secondary Schools. Report of the Sub-Committee appointed by the Science Masters' Association, 1922. (Oxford: University Press. Price 1s.)

and consideration by teachers in schools. The point in the report to which objection may be made is the rigid declaration that "set lectures giving mere information in a didactic manner should be avoided." Most teachers of science would agree that at an early stage the teaching of science should be mainly practical and objective. If it is not, the true spirit of scientific knowledge is lost. But why should the didactic manner be avoided? In the course of study in zoology, for example, why should there not be occasional lectures on some of those wild beasts of the world which naturally excite the interest of boys and girls. Lectures on whales, on kangaroos, on the great carnivores, on tropical insects, or even on the fauna of coral reefs, would surely be stimulating and instructive. Entirely to avoid didactic instruction is to make the teaching of science too parochial in character and to leave unsatisfied the thirst for knowledge of the wonders of the world beyond our own shores.

The new method may be admirable as a substitute for the older dry-as-dust didactic teaching, but it tends to lead into the new danger of discouraging boys and girls from reading about natural phenomena beyond the reach of their personal observation and about the thoughts and discoveries of the great men of science.

Human Character.

Human Character. By Hugh Elliot. Pp. xvi+272. (London: Longmans, Green and Co., 1922.) 7*s.* 6*d.* net.

WE are accustomed to judge of a man's character by his behaviour, that is to say, by the manner in which he reacts to the countless vicissitudes of everyday existence. In our experience these reactions differ according to the individual, and we interpret this variability of response by saying that the characters of the individuals affected are correspondingly diverse. Although character is an attribute of the man himself, it can only be known by the man's actions, and is a rough description of the mental and nervous constitution on which the reactions depend. This constitution is partly inborn, partly acquired. The pattern of the cells and nerve paths which make up the central nervous system is already laid down before birth, but the resistance which any impulse meets with in its passage through the central nervous system is the resultant not only of the inherited pattern, but also of experience, every reaction which has occurred having left some trace of its passage and produced facilitation along certain paths and blocking of certain other paths.

Character is thus a product both of nature and of nurture, the former supplying potentialities of behaviour, the latter limiting and modifying the extent to which any given reaction may take place. Although character is a question of the arrangement and resistance of a complex system of neurones, the only possible way of describing it is in terms of the reactions which it is able and wont to produce. Without taking a dynamo to pieces and measuring the physical properties of its various parts, the only method by which we could describe its potentialities would be by making it work and finding out what current and what electromotive force it gave us at varying speeds of rotation, *i.e.* by its performance; and the same holds good for any attempt to describe under the term of character the complex structural arrangements which determine the reactions of a man. Character itself we cannot with any accuracy describe or classify, but we can analyse the different factors, mental or physiological, which are involved in its formation and determine behaviour. This is the manner adopted by Mr. Hugh Elliot in the book now before us.

Since character determines behaviour, it is possible to form an idea of the essential nature of human character by analysing the motives which determine human action. The older philosophers (and their teaching is reflected in current thought) were wont to draw a marked distinction between the actions of animals, which were determined by instinct, and those of man, which were guided by reason; whereas we have now recognised that the intellectual processes of reasoning have very little to do with behaviour. Although the emotions have long been described as the springs of action, the preponderating and almost exclusive rôle of emotions in determining human activities has only been fully recognised during the last twenty years. Emotions are the representation in consciousness, the subjective side, of the complex series of automatic reactions which in animals we call instincts and which in their case we only occasionally endow with emotional attributes. Thus the quest for food, flight from an enemy, pursuit of a mate, are all automatic reactions which are shared by man with the lower animals, but in the former case we say they are due to the emotions of hunger, fear, or love.

In the first chapter of this book, which Mr. Elliot entitles "General Principles," the author emphasises the all-importance of the emotional states in the determination of behaviour. Man's life thus becomes a series of instinctive reactions differing from those of the lower animals only in their greater complexity, and in the extent to which they are varied as the result of individual training or education. Reason does not dictate behaviour. Party government would be impossible if this were the case, nor would two nations

like the French and English advocate diametrically opposite methods of dealing with the same problem. Reason is but the instrument for the safer and more successful carrying out of a reaction which will satisfy the prevailing emotion, and it is to the emotional conditions of the electors or of different nations that politicians and statesmen have to appeal if they wish to get support for any particular line of action. Volition itself is another word for desire. A man with a strong will is one in whom all the faculties of the mind are slaves to the satisfaction of a dominant desire, which may be easily attained or may take years for its achievement. The author points out that what a man does is the resultant of what he feels, and since feelings are themselves dependent on external conditions of the individual, character is but an abstraction, a name for the average mental manifestations and not representing anything fixed or constant.

Theoretically it might be thought possible to build up a logical account of character, starting from the primitive instincts tending to the preservation of life, to reproduction, and to the association with other individuals in communities (the herd instinct), by showing how these are modified to produce the manifold variation of impulsive behaviour observed in man. Such an attempt would, however, involve us in constant cross-reference, since every quality of the mind is bound up with other qualities, just as every part of the brain is associated in its activities with those of all other parts. The only method left is that adopted by the author, namely, taking the more complex emotional conditions, to analyse their composition, their relationship to other mental states, and their manifestations in conduct. Such a method renders it difficult to preserve logical continuity in the treatment of the problem. Each chapter becomes an essay in itself, as is evident from a consideration of the headings in the table of contents. The first seven chapters, for example, are labelled as follows: General Principles, The Major Passions, Egoism, Love, Social and Moral Feeling, Jealousy, Religion.

There are altogether twenty-two chapters, but the treatment is much more connected than would appear at first sight from the headings just detailed. Throughout the book the point of view of the author is that of the educated amateur, so that the reader feels that he is capable of following the arguments and appreciating them critically, and indeed that he is entitled to differ from the author without presumption. After all, the most readable books are those in which the reader is only half in agreement with the author, so that he is incited to think for himself, and to form his own conclusions on the subjects dealt with. It will do no one any harm to try to analyse in the same manner in which the author has accomplished it the motives for his own actions and for those of other people. It may indeed tend to make reason play rather a larger part than has hitherto been the case.

It is curious that the author at the beginning of the work abandons the analytic method when speaking of the moral feelings. He says: "The moral emotions are a deep and powerful instinct, buried in every mind, and so much part of our constitution that we are almost unaware of their very existence. We refrain from wrong-doing as the result of a deep emotion which controls our actions, very often unknown to ourselves." This is in other words the popular idea of conscience, which is regarded as implanted in man from his birth. But surely, when the author speaks of "wrong"-doing he is begging the whole question. The moral instinct is the impulse to act in accordance with the rules of the tribe of which the individual is a member, and is developed by education, in its broadest sense, from the herd instinct. On this instinct depend the appreciation of approval and the seeking of support from the other members of the community. By education, by mimicry, by the repetition of enforced actions, by the experience of the painful results of some and the pleasurable results of other actions, the herd instinct is so moulded that the easiest reaction to commonly recurring circumstances is one that is in accordance with the rule of the tribe, and any anti-social action is attended with mental discomfort or anticipation of punishment or disapproval. This is what is commonly called conscience. The moral sense will thus be quite different in men of different races, according as they have been brought up in a Hindu or Christian community or among savages. The potentialities of development of this moral sense, this *Sittlichkeit*, will vary from individual to individual, but the content of the sense and its results in action will depend on the environment of the man from his birth.

The book is copiously illustrated with quotations from Shakespeare, Dante, and Goethe. The author points out that great writers, far more than men of science, penetrate human nature, and that of all writers Shakespeare possessed the most profound insight into character. The upshot of the whole work is that a man's character depends on his feelings. Feelings are the springs of action; education is above all a development and training of feelings. It matters more what a man does than how he does it, and it is probably on this account that the English system of education, so deficient on the intellectual side, can boast of results in many ways more successful than those achieved by the Lycée or Gymnasium.

E. H. S.

The Arabs of the Sudan.

A History of the Arabs in the Sudan: and Some Account of the People who preceded them and of the Tribes inhabiting Dárfūr. By H. A. MacMichael. Vol. 1. Pp. xxii+347. Vol. 2. Pp. viii+488. (Cambridge: At the University Press, 1922.) 2 vols. 90*s.* net.

THE two volumes before us present the result of Mr. MacMichael's investigations in the Northern Sudan carried on for nearly twenty years, and they may be regarded as the logical continuation of his earlier work (published in 1912) on the Arabs of Kordofan. The present work deals with all those Sudanese tribes in which Arab blood preponderates, or at least warrants the popular conception of them as Arabs.

Mr. MacMichael's area of study—roughly north of 12° N. and west of 25° E.—is so entirely his own, his conclusions so largely the result of original field work, that any detailed criticism is impossible. All that the reviewer can do is to give some idea of the scope of the book, the author's general conclusions, and where possible indicate how far these agree or disagree with the results of workers in other parts of the Sudan.

The plan of the book is unusual; the second volume consists of the translations of thirty-two native manuscripts, for the most part *nisba* "pedigrees," with explanatory notes and genealogical trees. The first volume, with the exception of sections dealing with the early history of the Nile Valley, and the non-Arab races of Darfur, is devoted to a series of dissertations or essays based on the data contained in the manuscripts in volume 2, and the study that the author has made of literary sources both Arabic and European.

Wearisome as these *nisba* are to read—and the student will be inclined to echo the sixteenth-century writer of document BA, "the knowledge of the pedigrees of persons who are unrelated to yourself is of no use"—their value is increased by their rarity, for though many Sudan Arabs are prepared to produce fragments of paper which they regard as of genealogical interest, relatively few documents of real historical value have survived the ravages of white ants and the accidents of the nomad life. Moreover, of those that did exist half a century ago, very many were burnt during the Dervish rule by the orders of the Mahdi, who feared that research might tend to invalidate his pretensions to be the Expected One, and by the Khalifa, a Baggara from Darfur who was interested in genealogy to the extent only of not desiring to appear less nobly born than those over whom he ruled.

Not all the manuscripts are *nisba*: there is a "History of the Fung Kingdom" (MS. D7) of far more general interest, while somewhere between these and the "pedigrees" come the MSS. numbered DI and D3. The third part of the former, probably dating from the eighteenth century, contains much of general ethnological interest, while the latter, a series of biographies of holy men of the Fung period, written early in the nineteenth century, has considerable social and folklore value.

The first three chapters, dealing with the pre-Muhammadan inhabitants of the Sudan, go far back in time. Mr. MacMichael seems concerned to prove that there was a considerable inflow of Arabians into Egypt and the Sudan so far back as the Old Kingdom, but there is really no sufficient evidence for this, nor from the point of view of the present volumes is it of any importance, this alleged very early Arabian influence being ignored in the remainder of the work. The next two chapters deal for the most part with the Nubians and Beja and contain much that is interesting and suggestive, but the reviewer may be allowed to point out that the author is incorrect in attributing to him the view (1, p. 35) that "the Hadendoa are representatives of the Beni Amir stock modified chiefly by miscegenation with the tall negroes of the Nile Valley, and also, in all probability, with the . . . round-headed Armenoid population. . . ." There can be little doubt that it is Armenoid blood that is responsible for certain of the physical characters of the Hadendoa; negro influence has been but slight. In any case these three chapters are introductory only; they contain none of the author's own observations, so that they stand apart, and the critical attitude which they provoke rapidly dies down on reading the rest of the book.

The remainder of part 1 forms a most valuable introduction to the ethnology of the non-Arab races of Darfur; here Mr. MacMichael has done service not only by bringing together the scattered notices from literature, but also by the account he gives of the social organisation and religious rites which he has himself observed among the Dagu, the Fur, and the dwellers on Jebel Midob. Among these tribes, as well as among some of their even less known neighbours, rain-making ceremonies are still of importance, the rain-maker being a woman and descent being in the female line; moreover, in a general way their religious ideas, so far as it is possible to judge on present information, seem akin to those of the Nuba of Southern Kordofan, as observed by the present writer. This fact has not escaped Mr. MacMichael; it might have been added that the work of Tucker and Myers (Journ. Roy. Anthrop. Inst., 1910) suggests a definite physical relationship. Combining the information he collected from the various tribes of Darfur, Mr. Mac-

Michael concludes that the two main ethnic strains in the country are the negro and the hamitic, the latter being, at least in part, a result of the pressure exerted by Arab immigrants into North Africa upon the Berber tribes. Thus originated the ruling aristocracy of the states fringing the Sahara to the west of Lake Chad, while the Tibbu are to be regarded as an early Libyo-Berber mixture that has come to form the basis of the population of Northern Darfur, the negro element predominating in the south. It must, however, be remembered that cultural influence, perhaps relatively ancient, has come in from the east, as is evidenced not only by legends of origin but also by the very striking resemblance in the vocabularies of such peoples of Darfur as the Midob and Birked to those of the Barabra of the Nile Valley, and that with this, there was probably introduced a strain of foreign blood.

Turning now to the Arabs with whom the main bulk of the work is concerned, Mr. MacMichael begins by tracing their progress through Egypt in the Middle Ages. This is no easy matter, for even in the ninth century the historian, el Baladhuri, admits that there were great differences of opinion. Here may be quoted a dictum of the author of MS. DI: "The tribes of the Arabs who are in the Sudan, other than these [the Nuba, the Abyssinians, and the Zing], are foreigners, and have merely mixed with the tribes mentioned above and multiplied with them. Some of them have retained the characteristics of the Arabs, and the element of Nuba and Zing that is interspersed among them has adopted the Arab characteristics; and on the other hand there have been some Arabs who have become fused with the Nuba and the Zing, and adopted their characteristics; but in each case they know their origin."

Here, in brief, is the history of much of the Arab Sudan, and even if it be doubted that "in each case they know their origin" a great deal of Mr. MacMichael's research does but amplify and confirm his Arab forerunner. The whole process can be followed particularly well in the case of the Guhayna (Juhaina). In the pre-Islamic period they occupied Nejd and the neighbourhood of Medina, where a section dwell to this day. Many migrated to Egypt, taking part in the conquest with other sections of the Ḳuḍa'a, while two hundred years later they formed part of a force invading the Beja country. Some of them seem to have reached Aswan by the ninth century; by the fourteenth century they had penetrated far into Nubia, and it was the Guhayna who more than any other tribe brought about the dissolution of the Christian kingdom of Dongola.

"At first the kings of the Nuba attempted to repulse them, but they failed; then they won them over by giving them their daughters in marriage. Thus was their Kingdom disintegrated, and it passed to certain of the sons of the Guhayna on account of their mothers according to the custom of the infidels as to the succession of the sister or the sister's son. So their Kingdom fell to pieces and the A'rab of Guhayna took possession of it. But their rule showed none of the marks of statesmanship because of the inherent weakness of a system which is opposed to discipline and the subordination of one to another. Consequently they are still divided up into parties and there is no vestige of authority in their land, but they remain nomads following the rainfall like the A'rab of Arabia. There is no vestige of authority in their land, since the result of the commingling and blending that has taken place has merely been to exchange the old ways for the ways of the Bedouin Arab." Thus Makrizi in a passage not included in de Slane's translation.

It was this dual policy of following the rainfall and of inter-marriage that led to the rapid spread of the stock, so that a sixteenth-century author, or more probably copyist, writes of a total of "fifty-two tribes in the land of Soba on the Blue Nile under the rule of the Fung," while there were even more in the west, including Bornu. So at the present day all the Baggara, including those of Darfur and Wadai, regard themselves as united in the common bond of Guhayna ancestry. It is in this sense that the Guhayna constitute one of the great moieties of the Sudan Arabs, yet it must be remembered that in the Sudan the tribal name Guhayna is used in a narrow as well as a broad sense. In the former it is restricted to certain nomads inhabiting the Sennar Province; it is only in the widest sense and by much manipulation of genealogies that it is stretched to include the Baggara and the vast group of camel nomads in Kordofan, all of whom if pressed will say that they are descended from Abdulla el Guhani.

The other great division of the Sudan Arabs, even larger and more loosely knit than the Guhayna, is the Ga'aliin, the members of which claim to be descended from 'Abbas, the uncle of the Prophet. In the main this group is sedentary; the Arab element *sensu stricto* that went to form it seems to have coalesced with the older settled inhabitants of Nubia and to a considerable extent to have adopted their social habits. Indeed, Mr. MacMichael applies the term Ga'aliin-Danagla to this, the other great moiety of Sudan Arabs, which includes most of the riverain tribes as well as a number of sedentary tribes in Kordofan.

It must be understood that the reviewer has been able to touch on some only of the outstanding features of this remarkable book, which, while holding so much detailed information, abounds in suggestions which

will make it a source of inspiration to every worker in the field of which it treats.

A word of tribute should be paid to the Sudan Government for its enlightened policy in guaranteeing the amount necessary to permit publication.

C. G. SELIGMAN.

The Utilisation of Coal.

The University of Sheffield: Department of Fuel Technology. Coal: a Series of Lectures on Coal and its Utilisation. By H. Chamberlain, J. W. Cobb, R. Lessing, F. S. Sinnatt, and M. C. Stopes. Pp. iii +41. (London: The *Colliery Guardian* Co., Ltd., 1922.) 5*s*.

THIS publication in book form of the series of lectures on coal and its utilisation, delivered recently under the auspices of the Department of Fuel Technology of the University of Sheffield, renders the lectures available to a larger audience than that to which they were originally addressed. Each one is the work of an authority of acknowledged eminence in the particular branch of the subject treated, and, while of course containing nothing absolutely new, presents a clear and accurate picture of the present state of our knowledge brought thoroughly up-to-date. Perhaps the chief cause for regret is that the head of the Department of Fuel Technology, Prof. Wheeler, did not himself contribute to this series of lectures.

The first lecture, by Dr. Marie Stopes, deals with the subject which she has made peculiarly her own—the constitution of coal and the identification of the four constituents which she has isolated. This classical piece of work, at first merely of scientific interest, is gradually assuming an aspect of economic importance owing to the widely different properties of the various constituents. Wheeler and Lessing have shown, for example, that the coking property of coal appears to pertain almost wholly to the clarain and vitrain, fusain being quite and durain almost completely non-coking. At the same time, other researches would indicate that methods of separating these constituents on a commercial scale are at any rate possible of attainment, a measure of success having already been achieved in this direction by means of froth flotation. It is obvious that such a process may present great industrial possibilities and that it should be capable of greatly increasing the available supplies of coal suitable for the production of good metallurgical coke. Dr. Marie Stopes has not herself discussed this aspect of the question, although it is referred to in some of the later lectures; it may, however, be admitted that it is scarcely ripe yet for anything more than the passing reference which it here receives.

It is probably not the fault of Mr. F. S. Sinnatt, who deals with the preparation of coal for the market, that his subject is so wide that it is impossible to do anything like justice to it in so short a space; hence the lecture is necessarily of a sketchy character, and gives but little indication of the more modern developments of this important branch of technology. Mr. Sinnatt devotes a paragraph to the method of froth flotation, but does not attempt any discussion of the theoretical principles upon which this process is based; indeed, throughout his lecture he omits any explanation of the scientific principles upon which the various processes depend, though undoubtedly such discussions would have added very much to the value of his contribution.

The third lecture, by Dr. R. Lessing, is on the carbonisation of coal. The four main products of the decomposition of coal—the solid, the viscous, the liquid, and the gaseous—are dealt with, and the importance of each is pointed out, and the effect upon it of the different methods of conducting carbonisation. Dr. Lessing gives a full account of his own method of carrying out laboratory coking tests and indicates their practical application; at the same time he shows clearly the difficulties of following in detail the course of the coking operation on a large scale owing to its great complexity and to the number of varied changes that are taking place simultaneously. This is a very wide subject and one of very great importance; it may be noted that almost simultaneously with the appearance of the work under review, the Society of Chemical Industry has published an important paper by Sir George Beilby on the structure of coke, its origin and development, which is wholly devoted to the minute study of a detail which Dr. Lessing is perforce compelled to dismiss in a few lines. Dr. Lessing's lecture concludes with a review of the three types of industrial carbonisation, in gas works, in coke ovens, and in low temperature plant, although it may well be held that the term "industrial" is much too flattering a term to attach to the last-named process as it exists to-day.

In the fourth lecture Mr. Horace Chamberlain deals with the purification of coal gas from the gas-maker's point of view; his contribution is in every sense an admirable one, clear, concise, and yet setting out the principles of the various processes in sufficient detail. Perhaps the only cause for regret is that he has passed over the Burkheiser process for the utilisation of the sulphur in coal gas in somewhat too summary a fashion. It is true that this has not been a success up to the present, but it is by no means impossible that the process may contain the germs of a highly successful practice in the future.

The last lecture, by Prof. Cobb, is on ammonia from coal, in which the author shows clearly, as the result of

much experimental work, the conditions under which the maximum production of ammonia may be obtained by the decomposition of coal; it need scarcely be said that the subject is one of the greatest importance, having regard both to the great manurial value of the product for agricultural purposes and to the highly important part that it plays in the economics of coal carbonisation. The lecture concludes with a brief review of the present position of the synthetic processes for the production of ammonia, the chief protagonists being the Haber and the Claude processes; Prof. Cobb evidently holds the view that there is likely to be but little to choose between the costs of production of ammonia from coal and by synthetic methods, and that it is as yet impossible to say on which side the advantage will ultimately rest.

While each of the lectures is a complete little monograph in itself, the subjects have been carefully selected, so that the book as a whole covers well a large portion of the field included under the comprehensive title of the Utilisation of Coal, a subject which is of the greatest national importance at the present moment. It has often been said that British coal has been too cheap in the past, and that we accordingly got accustomed to squandering recklessly our greatest national asset: such habits of extravagance, once acquired, are not easily got rid of, but works like the one before us have at least the great merit of indicating the right road to a much-needed improvement in this respect.

H. LOUIS.

Astrology of Comets.

Tychonis Brahe Dani: Opera Omnia. Edidit I. L. E. Dreyer. Tomus iv. Pp. 377-524. (Hauniae: Libraria Gyldendaliana, 1922.)

IN these pages Dr. Dreyer has given us an interesting collection of papers on comets, not hitherto accessible to the learned world. After the concluding page of the well-known "De Mundi Ætherei recentioribus Phænomenis" we have a treatise of sixteen pages in German, now printed for the first time, on the comet of 1577. Next come nine pages in Latin on the comet of 1585, printed at Uraniborg in the "Diarium astrologicum et metheorologicum" of Elias Olai Cimber for 1586, and seven pages in the same language now first published on the same comet. These last two treatises are mainly astrological, as is no small part of the treatise on the comet of 1577.

The largest part of the present fasciculus is, however, occupied with a controversy on comets between Tycho Brahe and the Scottish physician John Craig. Tycho had sent Craig a copy of his printed but as yet unpublished work, "De Mundi . . ." and Craig had replied in certain letters which as Dr. Dreyer informs us were published by Noltenius in 1737. These drew from Tycho an "Apologetica Responsio," filling sixty pages of the present volume. The work was printed and a few copies were sent to friends. It was Tycho's intention to include it along with the whole controversy with Craig as a supplement to his "De Mundi . . .," but his representatives wisely decided to let the main treatise go forth by itself. No printed copy of the "Apologetica Responsio" has survived, and Dr. Dreyer has edited it from a MS. at Copenhagen. Craig replied to this work in a treatise entitled "Capnuraniae restinctio," of which Dr. Dreyer has been able to give us a fragment from a Vienna MS. The task of replying to this work was ultimately undertaken by Kepler, but abandoned by him on Tycho's death, though Kepler's unfinished reply has since been published in his collected works. Dr. Dreyer's notes on the whole volume, including the "De Mundi . . .," occupy the last thirty-two pages of the present publication.

Not the least instructive of these studies are the astrological treatises. It will be observed that with the exception of the paper written for his assistant, Tycho early abandoned the intention of publishing them. In an age when nearly all science was based on an experience not supported by carefully recorded experiments and observations, it was reasonable to give to the supposed truths of astrology the same respect that was shown to scientific teaching generally. Tycho's astrology is neither fanciful nor arbitrary, but professes to regard observation as the test of truth. Thus on p. 413 he refuses to decide on the limits of the clima of Saturn, because they rest on no sufficiently attested experience. On the other hand, he regards it as a settled fact that the comet which was seen in Aries in 1533 changed the religion in Britain and caused lasting discord. Whatever value Tycho may have attached to such speculations, he could not but feel that they were work of a very different class from the great astronomical edifice founded on his own observations of precision.

The controversy with Craig is not without its analogies. Craig held with Aristotle that objects in the ether were immutable, while objects in the elements might suffer change, and that temporary phenomena like comets must, therefore, be sublunar. Tycho Brahe held that from the relative slowness of their motion and the absence of perceptible parallax they must be more distant than the moon. The question is of the ever recurrent type where observations seem to conflict with a general principle which has hitherto known no exception.

Our Bookshelf.

An Inorganic Chemistry. By Prof. H. G. Denham. Pp. viii+684. (London: E. Arnold and Co., 1922.) 12*s.* 6*d.* net.

PROF. DENHAM has written "An Inorganic Chemistry" for intermediate students. In this field at least half-a-dozen excellent text-books are already available; but, perhaps for commercial reasons, additional volumes of similar scope continue to be produced, and the process may be expected to continue until each leading publisher is able to offer a book of this type. Prof. Denham's book is well printed and nicely illustrated, and in this respect compares favourably with other competing volumes.

The author claims as a simplifying factor the introduction of the periodic classification of the elements in the middle (instead of at the end) of the chapters on the non-metals; but it is doubtful whether this policy will be followed by other authors, because it is obviously difficult to classify the elements when only two groups of them have been described. The policy of including a brief description of all the less common elements (except those of the "rare earths") is also of doubtful value, in view of the great difficulty which intermediate students find in becoming acquainted even with the common elements when they pass from the study of the non-metals to that of the metals. More important perhaps is the fact that while atomic weights are given at a very early stage, Avogadro's hypothesis and the molecular theory are postponed to Chapter IX., with the result that for nearly 100 pages hydrogen gas is represented as H and oxygen gas as O; in the meantime, subjects such as the theory of solutions and thermo-chemistry, and even valency and structural formulæ, are discussed on this very inadequate basis.

The author's attention may be directed to the incorrect statements which result from his undue simplification of crystal forms, which he classifies by means of planes of symmetry instead of by means of crystallographic axes. It would also be well if it were clearly stated that the vapour-pressure curves of the different forms of sulphur are purely fictitious, although they are presented in the same attractive form as the solubility diagrams, which are a pleasing feature of the book; it may be suggested that the omission of the small squares might be used to distinguish those diagrams which are mere sketches from those where accurate data are given. T. M. L.

Happy India as it Might Be if Guided by Modern Science. By A. Lupton. Pp. 188. (London: G. Allen and Unwin, Ltd., 1922.) 6*s.* net.

MR. LUPTON in a single cold-weather tour through the Indian Empire has tried to solve a series of economic problems, which have long engaged the attention of administrators and men of science. He is impressed, as all thoughtful observers of Indian life must be, with the general poverty of the people, their exhaustion by malaria, and their inability to resist periodical scarcity. The soil is ineffectually cultivated by weak plough cattle, the produce is extremely low when compared with that of other more fortunate countries, and much of the scanty manure is used as fuel. Here is the chance of science. Why not have a chemical examination of the soils of each district to find out what constituents are lacking? Why not establish a fuel reserve in each village? Why not lay down at every peasant's door wood from the Himalayas or coal from Bengal? Why not use electricity to pump water from the wells? Why not fill every puddle and so abolish malaria?

These are admirable schemes, but unfortunately the Government does not possess the means of raising enormous loans, paying the interest, or maintaining a new army of officials, in the hope that some day it will be repaid for the cost of 7,000,000 tons of superphosphates which he proposes to import, even if such a demand did not upset agriculture all the world over. It is very well to say, spend a few millions as a beginning, but this would do little to improve the situation, and, as he admits, there is little use in giving ignorant people superphosphates if you do not at the same time supervise their use by a corpus of experts. Even to make a fuel reserve in a village means taking up arable land for this purpose, and the peasant does not like reserves because they shelter wild pig, monkeys, and green parrots, his greatest enemies.

Mr. Lupton honestly admits that the Government is not to be blamed because every Hindu marries and rears a family, resulting in congestion of the population. He hopes vaguely that public opinion will check this abuse, but he admits that the educated Indian gentleman knows or cares little about the peasantry, and that "if the Indians govern themselves, we may be sure that their government will be bad." Mr. Lupton is to be commended for his good intentions, his fine sense of humanity, but it needs practical wisdom to consider the problems which he has attempted to solve.

The West Riding of Yorkshire. By Bernard Hobson. Pp. xii+188. (Cambridge: At the University Press, 1921.) 3*s.* 6*d.* net.

MR. BERNARD HOBSON had a difficult task to describe the West Riding of Yorkshire owing to the wealth of the material. The term "Riding" means one-third, so that the area dealt with is only one-third of the county of Yorkshire; but as it includes the densely populated coalfield to the south and the limestone moors to the north-west, it contains areas of special importance and interest. Mr. Hobson has not only compiled an instructive summary of the geography, geology, and history of the West Riding, but has also presented it in a form interesting throughout. The most important geographical feature of the area is the Pennine Range, forming its western highlands, which is unique in England from the extent of its subterranean river system. The industrial districts include many important cities; the author's account of Sheffield is of especial interest. The history of man in the area dates from Neolithic times, for Mr. Hobson tells us that no undoubted trace of Palæolithic man has yet been found, though abundant remains occur only three miles from the Yorkshire border. The area is especially rich in archæological and historical monuments. In the chapter on the architecture it is remarked that the professional architect arose in the period of James I., before which building had been in the hands of the builder and the craftsman. Apparently, therefore, the end of the great age of building in England synchronises with the rise of the professional architect.

A Laboratory Handbook of Bio-Chemistry. By P. C. Raiment and G. L. Peskett. Pp. 102. (London: E. Arnold and Co., 1922.) 5s. net.

THE book before us would be more appropriately entitled physiological than bio-chemistry, as in its scope it is almost entirely limited to the elementary physiological chemistry usually taught to medical students. A short theoretical account of each subject precedes the practical work. Much of this is quite sound, but the text is frequently marred by looseness or inaccuracy of statement, which requires stringent revision before the book is placed in the hands of a student. Examples of this will be found in the account of the action of acids on soaps (p. 45), the precipitation of globulins (p. 24), the properties of the albumins (p. 16), and elsewhere. Again, histidine is omitted from the list of amino-acids derived from proteins, vitamin B is stated to be associated with the fatty radicles of milk, and so on.

The practical work is almost entirely confined to qualitative test-tube experiments, the chief exceptions being the quantitative methods of urine analysis, and, in an appendix, Kjeldahl's method and the methods for estimating reducing sugars. These experiments are clearly described and easy to perform.

We do not, however, believe that practical bio-chemistry can be satisfactorily taught in this way. Preparative work and, especially, quantitative methods are essential even in the earliest stages. Unless this kind of exercise is freely introduced the student will acquire no real grip of the subject, but will regard it simply as another dreary course of "test-tubing."

A. H.

Meteorological Office: Air Ministry. British Rainfall, 1921. The sixty-first annual volume of the British Rainfall Organisation. Report on the distribution of rain in space and time over the British Isles during the year 1921, as recorded by more than 5000 observers in Great Britain and Ireland. Pp. xxiv+300. (London: H. M. Stationery Office, 1922.) 12s. 6d. net.

RAINFALL statistics over the British Isles have now been collected and published annually for a sufficient period to render the observations of very great value, thanks to the foresight and persistent perseverance of the late Mr. G. J. Symons. Where observations do not exist, a shrewd approximation of the average fall can be obtained by means of neighbouring measurements.

The essential feature of the volume is a discussion of the drought in 1921, which was more remarkable for persistence than for intensity over short periods, although June and July were probably drier than any two consecutive months in living memory. In England and Wales 1921 was probably the driest year since 1788, and in London it was the driest for at least 145 years. The south-east of England experienced the greatest severity of the drought, and a part of Kent had for the year less than 50 per cent. of the average rainfall. A coloured map opposite to page 132 shows graphically for the British Isles the relation of rainfall in 1921 to the average of 1881–1915.

Rainfall is discussed in connexion with scarlet fever, and there is an article at the end of the volume on the fluctuations of annual rainfall.

C. H.

Design in Modern Industry: The Year-Book of the Design and Industries Association, 1922. With an Introduction by C. H. Collins Baker. Pp. 157. (London: Benn Bros., Ltd., 1922.) 15s. net.

THE Design and Industries Association, of which this appears to be the first Year-Book, is concerned with liaison work between the artist, the manufacturer, and the distributor, and aims at the improvement of British design through the intelligent and liberal use of the artist, both for ideal reasons and to meet foreign competition. The Association holds that good design is tested first and chiefly by fitness, and secondly by pleasantness in use. A teapot, for example, should have a spout that does not drip, a handle and spout that do not project unnecessarily (to save room in the cupboard and reduce risk of fracture), the lid should be securely held while the pot is in use, there should be the fewest, if any at all are necessary, of crevices and sharp angles, as these hold dirt and are difficult to clean, the cost should be reasonable, and so on. The illustrations include furniture, pottery, fabrics, kitchen equipment, metal work, printing, signs, tablets, shop fronts, etc. The designs as a rule are distinctly pleasing, and are appreciated by critical artists. The photographic reproductions are, with few exceptions, excellently done, but we hope that the Association in its second Year-Book will be able to introduce colour reproductions where they appear to be essential.

Alcohol in Commerce and Industry. By C. Simmonds. (Pitman's Common Commodities and Industries.) Pp. xii+119. (London: Sir Isaac Pitman and Sons, Ltd., 1922.) 3s. net.

THE late Mr. Simmonds had produced a larger and more detailed treatise on alcohol before undertaking the present small volume. It would therefore be anticipated that his treatment of the subject would be most expert. The present volume, in fact, is a wonderfully concise and complete account of the manufacture and uses of alcohol, and is well illustrated. It is perhaps scarcely realised by those not familiar with recent progress in chemical industry and engineering how many uses are found for alcohol, and how many more promise to be discovered. Mr. Simmonds's book will supply this information to the general reader, and the chemist will also find much that is useful in it.

Mathematics for Engineers. By W. N. Rose. (The Directly-Useful Technical Series.) Part I., including Elementary and Higher Algebra, Mensuration and Graphs, and Plane Trigonometry. Pp. xiv+514. (London: Chapman and Hall, Ltd., 1922.) 10s. 6d. net.

THE first edition of this work appeared in 1918, and was reviewed in our columns (NATURE, vol. 101, p. 463). It has now been put to the test alike by teachers and students, and has proved its value. The third edition, now before us, has been thoroughly revised; there are few additions, but we note one on elementary determinants which contains enough to enable the reader to understand certain methods employed in works on aerodynamics.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

On the New Element Hafnium.

In a former letter to NATURE (January 20, p. 79) we announced the discovery of a new element with atomic number 72, for which the name hafnium was proposed. Evidence was given that this element is a homologue of zirconium in accordance with theoretical expectations (Bohr, "Theory of Spectra and Atomic Constitution," p. 114, Camb. Univ. Press, 1922). Continued experiments enable us to complete the statements in the former letter. By the addition of a known quantity of tantalum (73) to our samples, and by a comparison of the intensity of the Ta-lines with the Hf-lines, a closer estimate of the amount of hafnium present has been obtained. We have investigated a great number of zirconium minerals from different parts of the world. They all contained between 5-10 per cent. of hafnium. In samples of commercial zirconium oxide investigated, we have found the new element, amounting in one case to as much as 5 per cent. Starting from the latter substance, by means of a chemical method which is also adapted to separate zirconium from the other tetravalent elements, we have been able to obtain several grams of a preparation in which the presence of about 50 per cent. of hafnium could be established. Conversely, we have succeeded in preparing zirconium in which no hafnium lines could be observed. Further particulars about the method of preparation and provisional determination of the atomic weight will be published shortly in the communications of the Copenhagen Academy.

G. HEVESY.
Universitetets Institut for teoretisk Fysik,
Copenhagen, January 31.

The Latent Period in Lubrication.

Sometimes in a scientific inquiry results accrue which are called, in laboratory slang, "pretty"; the pieces of the puzzle have fallen together in a fashion so pat as to give artistic pleasure.

Most lubricated surfaces have the curious property that the friction falls after the lubricant has been applied, until a steady state is reached after an interval which may vary from a few minutes to a few hours. For example, a clean surface of glass lubricated with pure heptoic acid, the slider being in position, the initial value of the coefficient of friction at 12° was $\mu=0{\cdot}51$, but in 40 minutes it had fallen to its steady value, $\mu=0{\cdot}40$.

This latent period, as it may be called, is shortened by a rise in temperature and, apparently, by mechanical agitation; and is manifested by surfaces lubricated only by a film of insensible thickness as well as by those flooded with liquid.

The most striking fact, however, is the influence of the slider. The final steady state is never reached unless the slider is in position. Surfaces which have been freely exposed to vapour or to an excess of fluid resting on them always have high friction when first put in contact. The lowest value is given only by a film of lubricant which has been enclosed for some time between two solid faces. Such is the puzzle, and the explanation is curiously simple.

A molecule of an aliphatic acid or alcohol is like a rod loaded at one end. Putting a drop of one of these substances on a clean surface is like flinging a handful of such rods, picked up at random, at it; some hit and stick by the loaded ends, others by the unloaded ends. Condensation from the vapour is similar except that the rods are flung singly.

It is practically certain that friction is lowest when all the rods are orientated in the same way, a condition which will be reached only when the wrongly orientated molecules have had time to evaporate off into the fluid or vapour and have been replaced by molecules rightly orientated. The latent period is the time occupied by this readjustment.

So long, however, as the layer is exposed to fluid or vapour it is always losing or gaining molecules by evaporation and condensation, and some of those arriving will be wrongly orientated. The layer will reach a steady state, but it will not be that of least friction because at any moment a fraction of the molecules will be wrongly orientated. Orientation will be as perfect as possible and friction at its lowest only after a layer has been for some time shielded from evaporation by being enclosed between solid faces.

If this explanation be correct there should be no latent period when both ends of the rods are alike. This is so. In normal paraffins both ends are alike, *and in no circumstances do surfaces lubricated by normal paraffins show a latent period.*

The fact that a latent period exists is of importance to practical lubrication. The molecular process which causes it is, we believe, of importance in the mechanics of living matter. Physiologists will note how it recalls du Bois Reymond's theory of muscle and nerve.

The Rule of Priority in Nomenclature.

In NATURE for February 3, p. 148, Mr. F. Chapman mentions three distinct proceedings that may affect the stability of nomenclature in zoology. Concerning those that arise from differences of opinion as to the classificatory value of certain shapes or structures, or those that depend on the advance of knowledge, on corrections of fact, or on the need for breaking up unwieldy groups, it is useless to argue. No system of classification and nomenclature devised by man can cope with such inevitable changes.

The third proceeding, with which alone I venture to deal here, is the discovery that a name in general use was predated by a name that hitherto has been left in obscurity, and the consequent enforcement of the law of priority. On this point Mr. Chapman's letter overflows with good sense; but it has all been said before. His laments, however, will not have been entirely wasted if you will permit this consolatory reply—namely, that in the year 1913, at the International Congress of Zoologists in Monaco, an agreement was reached in the largely attended section on nomenclature and confirmed in plenary session, by which the International Commission on Zoological Nomenclature was given power, on certain conditions, to suspend the rules in those cases where their operation was contrary to the general convenience. The Commission has, on the request of various

zoologists, already taken action in several cases. It has, for example, recommended, but not yet passed, the suspension of the rules in the case of Holothuria *versus* Physalia (Opinion 76), and is at the moment preparing to adjudicate on the name of the common house-fly (see NATURE, January 27, p. 115).

The Commission has also—urged thereto by its devoted secretary, Dr. C. W. Stiles—attempted to draw up for various groups lists of agreed and unalterable names, *Nomina conservanda*.

If, owing to the war and the peace, so thorough a worker as Mr. Chapman can have, apparently, forgotten or remained ignorant of the Commission's work, there must be many in the rising generation to whom it is equally unknown. If they cannot find what they want in the Report of the International Congress of Zoologists or, more accessibly, in the American periodical *Science* and in the Smithsonian "Miscellaneous Collections," they may like to know that the present members of the Commission in this country are Dr. Hartert and Dr. Jordan of Tring Museum, Dr. W. E. Hoyle of the Welsh National Museum, and myself at the Natural History Museum; also that the Commission is seeking to fill one of its vacancies with an Australasian representative.

F. A. BATHER.

The Formation of Coloured Bows and Glories.

WHEN favourably situated, a person may see rings of coloured light round the shadow of his own head, as cast upon a neighbouring fog-bank or cloud. These coloured rings or glories, as they are called, have been explained by previous writers as merely coronas due to particles near the surface of the cloud scattering light reflected from deeper portions of the cloud; in other words, the effect is regarded as of the same nature as the ordinary corona but due to secondary scattering. That this explanation cannot be accepted as correct is definitely shown by experimental observations made with artificial clouds.

The experimental arrangement is the same as that used by Mecke (*Ann. der Phys.*, vol. 61), and if the eye of the observer be placed on the same side of the cloud chamber as the source, so as to look down very nearly along the path of the beam passing through it, a succession of colours is seen along its track through the cloud. These colours also change as the angle of observation is changed; and the smaller the particle the greater is the angle from which they can be seen. The complete system of rings is obtained on illuminating the cloud with a beam of sunlight, and may be viewed in a perpendicular direction with the aid of a plane sheet of glass held at 45° in front of the cloud chamber, so that the observer's head does not screen the cloud chamber from the illuminating pencil. The observations prove that the phenomenon under discussion is shown by every position of the cloud, and therefore really arises from *primary* scattering by the droplets of water.

That the glories or brocken-bows arise in a way which is quite different from that of the ordinary transmission coronas is proved by the fact that the sequence of colours in the brocken-bows and in the transmission coronas due to cloud particles of the same size are far from being identical. The normal corona, due to larger drops, shows a central white field with a brownish-red edge, which is surrounded by the familiar coloured rings, but in the brocken-bows the arrangement is different and varies somewhat with the size of the drop. It is sometimes found that just round the central spot (which is the image of the source of light reflected from the first surface of the observing flask) there is a distinct minimum of intensity exhibiting colour; then the intensity increases, the colour being greenish-white bordered by a brownish-red edge, and then follows the usual succession of coloured rings as in the coronas. It is sometimes found that round the central spot there is a clear maximum, and then a belt of minimum intensity, and then again a maximum; in other words, there is an oscillatory distribution of intensity; in the central field of the brocken-bow only red and green rings or belts are present in different intensities, whitish-yellow colour being totally absent, while in the corresponding coronal rings the central field is yellowish-white or nearly without colour.

In order to understand how the glories are formed, we have to consider the light which travels back towards the source from the droplets. This arises in two ways: (*a*) by reflection from the front surface of the droplets; (*b*) by two refractions and one internal reflection. When a plane wave falls on the spherical particles and is reflected back at its external surface, the reflected wave front is strongly divergent, and, as a result, it merely adds a little to the general illumination of the field and does not give rise to any notable diffraction effect. But the wave front (*b*) formed by internal reflection is not so divergent as in (*a*), and is limited by a cusped edge, at which it is doubled back. When the droplet is small the path differences between back and front of the wave near the cusped edge are very small. Hence we may, without appreciable error, consider the wave front to be a simple spherical cap of appropriate radius. As a sufficient approximation, we may assume the centre of this spherical cap to be the image of a point placed on the axis at an infinite distance, produced by two refractions and one reflection. We have to find in directions making a small angle with the axis back towards the direction of the primary source the aggregate effect of this wave cap. The problem now is the same as the diffraction produced by a small circular opening in the screen on which light is propagated in spherical waves from a point source. We take as the axis of symmetry the line drawn from the source to the centre of the opening, and it is required to find the intensity of illumination at *any point* of a plane screen parallel to the plane of the opening and at a distance from the later. The detailed mathematical treatment of this problem is given in Gray and Mathews's "Treatise on Bessel Functions and their Applications to Physics," chapter xiv., and the result is applied in this case for the measurements of the positions of the maximum and minimum in the glory-rings. Considering the experimental difficulties and assumption in the theory, the results agree fairly well with the observations.

The Definition of Limiting Equality.

IN teaching the calculus to students of applied mathematics and physics I have found that the definitions of *limiting value* and of *limiting equality* given in practically all our text-books are unsatisfactory, and in my opinion inadequate. According to these books the test of limiting equality of two magnitudes is that their difference shall become less than any assignable *quantity*, however small. But this condition is satisfied by any two quantities whatever if they vanish simultaneously, and it affords no justification for the use of statements such as $dy = f'(x)dx$; on the other hand, if the quantities remain finite in the

limit the test appears scarcely to be necessary or useful in teaching elementary classes.

I consider that the proper test of limiting equality is that the difference between two quantities should become (numerically) less than any assignable *fraction of one of the quantities*, however small, in other words that $x - a < ae$ where e is any *fraction of unity*, however small (instead of $x - a < e$ where e is any *quantity*, however small), *the present definition being assumed to hold good even if the two quantities vanish or become infinite at the limit.*

If this condition be accepted as the definition of limiting equality, the same condition will hold good for any multiples or submultiples, however large or small, of quantities which tend to limiting equality, and also to sums of such quantities; thus if $x_1 - a_1 < a_1 e$, $x_2 - a_2 < a_2 e$, etc., then $\Sigma x - \Sigma a < e\Sigma a$ under all conditions. Such statements as $dy = f'(x)dx$ are to be interpreted as statements of limiting equality according to this definition, and we arrive at a definition of an integral as the limit of a sum of products, which is applicable not only to integrals of functions of a single variable, but also to integrals taken over areas, volumes, and indeed any of the *concrete magnitudes* which commonly occur in problems on mechanics and physics. Roughly speaking, this definition may be worded somewhat as follows:

Let x be any magnitude which can be divided into elements Δx, however small, y a measure associated with it such that if y_1 and y_2 are the greatest and least values of y associated with any element Δx, y_1 and y_2 tend to limiting equality when the magnitude Δx diminishes indefinitely. Then, since $(y_2\Delta x - y_1\Delta x)/y_1\Delta x = (y_2 - y_1)/y_1$, the products $y_2\Delta x$ and $y_1\Delta x$ also tend to limiting equality, and by the theorem for the limit of a sum, the sums of the products $y_2\Delta x$ and $y_1\Delta x$ taken over all the elements also tend to limiting equality and their common limit is defined as the integral $\int ydx$. Any single product can be legitimately designated by ydx in any equation, provided that this equation is interpreted as a statement of limiting equality in accordance with the above definition. A subsequent proof is required to cover cases of discontinuity such as occur, *e.g.* when finding the volume integral of a function which changes by a finite amount in crossing a surface.

In defining a differential coefficient and proving the formula for the differentiation of a product, I follow Fricke's method to a great extent. Fricke, however, defines $f'(x)$ by putting $x_1 \to x$ in $\{f(x_1) - f(x)\} \div (x_1 - x)$, but I consider it preferable to consider the more general fraction $\{f(x_2) - f(x_1)\} \div (x_2 - x_1)$. If this fraction tends to a unique limit when x_1 and x_2 approach a common limit x by any process whatever, this limit is defined as the differential coefficient of $f(x)$. This condition covers the cases where either x_1 or x_2 is first put equal to x and the other variable becomes equal to x subsequently.

G. H. BRYAN.

Museums.

THE article in NATURE of December 9 on "A Suggested Royal Commission on Museums" leads me to offer a few comments, based on recent experiences. It is trite to say that all museums are understaffed, but it may be worth while to point out some of the consequences of this condition. Being a student of wild bees (Apoidea), I have long been interested in the available collections of these insects. In 1920–21, I made a catalogue of all the species of bees in the British Museum, and also listed those at Oxford and Cambridge. Returning to America I catalogued the bees in the U.S. National Museum and the American Museum of Natural History. One of my principal objects was to bring about exchanges between these institutions, so I noted in most cases the size of the series. The authorities everywhere were extremely cordial to the exchange idea, and it was evident that if each museum would distribute its duplicates, which were often actually in the way, all would be greatly enriched, to the advantage of students on both sides of the Atlantic. Up to the present, it has been impossible to carry out the proposed plans, because the curators have been fully occupied in other ways. The prospects will necessarily remain unfavourable, so long as each man has many more duties than he can attend to. The staffs should be increased, and should include at least two types of men—those who are principally concerned with research and those who are primarily curators. The latter type, with a passion for collecting and arrangement, is not to be found everywhere, and is not produced by the universities. It involves, however, a high grade of ability, and should be zealously sought by heads of museums.

In their zeal for economy, many will object to increasing museum staffs. They ought to consider the matter as they would a factory or other commercial plant. A great deal of capital, material and otherwise, has been put into our museums. With a moderate increase of funds they can be made to function far more efficiently and develop more rapidly. The public policy has too generally been like that of a man who had built a house, and decided that he could not afford a roof. In some cases sheer poverty may afford an excuse, but even the United States, with all its wealth, treats its National Museum in the most niggardly manner. The truth is, that in a democracy the public will is the driving force, and an ignorant public has no will. It is the duty of scientific men to carry on a campaign of publicity, which need not involve anything detrimental to their self-respect.

One reform which I should much like to see at the British Museum (Natural History) is the establishment of a room of British entomology, with a special curator who made it his business to know the species of the country. As things are at present, the average collector is interested primarily in British species, but on going down to the Insect Room he has to appeal for help to a world-specialist in some group, who is perhaps monographing a particular family of beetles. Any one with a conscience hates to take much of the time of such a man for his relatively insignificant matters, and the specialist himself probably does not know the British Staphylinidæ or weevils. By assembling the British series in one room, in charge of a special man, or preferably two or three, the work of the amateur would be greatly facilitated, and young naturalists would not be blighted in the bud by a sense of the trifling character of their pursuits. This is not a criticism of the existing curators, whose courtesy and good nature under stress have often caused me to marvel.

Just to show the spirit of the place, I will relate a couple of amusing instances, which I myself witnessed. A man came to the department of insects with an account of a proposed patent for catching fleas by entangling their feet in the supposed perforations in diatoms. The nature of the markings on the siliceous framework of diatoms, and their relative size to the feet of a flea, were explained in all gravity and kindness, and presumably the new flea-powder never appeared on the market! Another day, a man came to the department of geology with a clay model of an

ox or some such animal, and I shall never forget the courteous way in which an eminent palæontologist assured him that the specimen should really go to the Museum at Bloomsbury, since a fossil would show only the bones, and not solidified flesh. The public certainly gets all it pays for, and more; but it could be much better served if it would pay enough to bring out the latent possibilities of the museum, which are doubtless greater than any of us can yet clearly imagine. University of Colorado.

Spiranthes Autumnalis.

IN the summer holiday of 1921, Mr. Mayland and I were astonished to find in the woods round Carrbridge, Inverness-shire, very sporadically but at two stations about a mile apart, specimens of the small orchid, *Spiranthes autumnalis*. We took some, and for two or three days their characteristic scent and spiral spikes interested our table in the hotel. I regret now that we did not preserve specimens: but I am pretty sure we were not mistaking the identity of the plant, as it was repeatedly the subject of remark, and I have known it since I was a boy.

I mention this non-recorded record because Sir Herbert Maxwell, who in September 1920 wrote to NATURE (vol. 106, p. 79), telling of a similar experience on Lower Spey-side; but in a later letter (vol. 106 p. 409), he expressed some uncertainty as to the identity of his plant as apart from *Goodyera repens*. Now when so acute an observer as Sir Herbert has arrived independently at the same conclusion as we did, I think the probability is strong that both diagnoses were correct, and that, though the specimens were not preserved as evidence, *S. autumnalis* has been found in an unexpected, non-calciferous locality.

Mr. Mayland tells me he sought it again in the following summer without result. F. O. BOWER.

The University, Glasgow, January 17.

The Scattering of X-Rays in Liquids.

IN various notes published last year I dealt with the scattering of light in transparent media, and showed that its study initiated by the late Lord Rayleigh in his theory of the colour of the sky has other fascinating applications in the explanation of the colour of the sea and other transparent waters, and of the colour of ice on glaciers. The thermodynamic theory of "fluctuations" developed by Smoluchowski and Einstein formed the starting-point in the discussions, but I was careful to emphasise the important complications arising from the anisotrophy of the molecules in fluid media and showed how the necessary corrections in Einstein's theory may be made. A considerable measure of success was attained in attempting to correlate the behaviour of substances in the liquid and gaseous states in this respect, and in predicting the effects due to alterations of temperature and pressure. The study of the changes in the intensity and states of polarisation of the scattered light in passing from the liquid to the solid crystalline state and their explanation forms another important line of inquiry in which some progress has also been made.

The purpose of the present note is to point out the relation between the optical effects referred to above and the very interesting recent work of Keesom and Smedt, who have obtained Laue photographs of various liquids traversed by a *homogeneous* pencil of X-rays (Proc. Roy. Soc. Amsterdam, 1922, page 119), and the similar work by Hewlett (*Physical Review*, December 1922, page 702), who used the ionisation method. Keesom and Smedt found that many of the liquids studied gave a well-marked diffraction ring at a considerable angle with the direct pencil. With liquid oxygen and argon, the first ring was formed at an angle of 27°. A weak second ring was also observed at 46° with oxygen, and at 49° with argon. With water, on the other hand, the second ring was very broad and diffuse and practically abutted on the first.

Keesom and Smedt have attempted to explain their results by various special assumptions regarding the relative positions of the neighbouring molecules, while Hewlett suggests that liquids possess something of a crystal structure. To the present writer it appears that the experimental results may be explained without any such special assumptions. As in the optical case, the liquid molecules may be regarded as the diffracting centres which are arbitrarily orientated and distributed uniformly in space subject only to such variations as give rise to density fluctuations in accordance with the Einstein-Smoluchowski formula,

$$(\Delta\rho)^2 = \frac{RT\beta}{V^2} \cdot \rho_0^2$$

where ρ_0 is the mean density $(\Delta\rho)^2$ the mean square of its fluctuations, R the gas constant, T the absolute temperature, β the compressibility of the liquid, and V the elementary volume under consideration. When traversed by a homogeneous pencil of X-rays the wave length of which is smaller than the average molecular distance, such a structure must give rise to diffraction rings which are more or less well defined according as the fluctuations of density are small or large. If in the expression for the density fluctuation, we take V to be a small cube with a molecule at each of its corners, the average fluctuation in its size and the resulting weakening of the diffraction pattern can be calculated somewhat on the same lines as in Debye's theory of thermal effect in X-ray reflection by crystals. In Keesom and Smedt's experiments, the low temperature in the case of liquid oxygen and argon, and the consequently diminished fluctuations of density must have helped in improving the definition of the diffraction ring of the second order. C. V. RAMAN.

"Artificial" Vertical Beam.

THE vertical beam through a low sun is generally referred to the reflection of sunlight from the basal surfaces of thin plates of ice which are falling through the atmosphere with their crystal axes vertical and horizontal. It has been the writer's good fortune to examine such reflections from individual "plates" that were slowly falling within a metre or so of the observer. Most of the plates were asymmetric portions of flat crystal growths, and they spun rapidly as they fell, with a motion resembling that of a falling maple-key. In this case, the vertical beam was observed to spread out slightly as it receded from the sun, and the angle subtended by the edges of the beam was obviously the complement of the vertical angle of the "cone" swept out by the rapidly rotating, but slowly falling flake.

An interesting "artificial" example of (probably) this phenomenon, was noted by many observers at the burning of two buildings at the Sydenham Military Hospital at Kingston, Ontario, on the night of January 3, 1923. The structures burned fiercely in the brisk north-east wind and lit up the snow-covered country for miles around. The unusual brightness may be judged from the credible report that people more than a mile from the fire easily read newsprint by its light. A very light snow-fall was barely noticeable from time to time during the evening. Out of the glow of the fire-lit smoke clouds there appeared to rise a vertical parallel beam of light, that with varying distinctness was visible for the three or four hours

during which the fire raged. It was visible from points near the fire—a few hundred yards—but was more striking from points a quarter to a half a mile away, from which the flames themselves could not be seen. It seemed to vary with some atmospheric condition (more or fewer snow crystals in the air ?) as it might be dim when the diffuse reflection of fire-light from the low-lying clouds would be brightest, and might be sharp and bright during a lull in the flames. It was, however, often most striking when the conflagration was at its height.

It was not due to shadow of the still-standing walls —the light coming from the burning interior—for it was first noticed when the roof had just caught fire and most of the light came from the burning shingles —a case where no wall shadow was possible. Further, the beam was sensibly parallel-sided. A wall-shadow would have given a broadly diverging beam. The explanation offered is that of reflection from falling flat snow crystals, which, of course, were not over the burning building but were distributed in the atmosphere between the observer and the source of light.

The official record at the Queen's University station of the Canadian Meteorological Service, taken just before the fire broke out and less than a mile from Sydenham Hospital, gave "Temperature 12° Fht., Wind N.E. 20 miles per hour, Light Snow." In fact, the snow-fall was so light that the record of precipitation over the twelve hours, including the time of the observations on the beam, was only 0·03 inch.

Unusual Crystals.

THE following may be of interest to readers of NATURE:

I have a bottle of pure phenol which has not been opened for a dozen years. During this period I have been interested to watch the growth of crystals from the sides of the empty portion of the bottle by sublimation. These crystals are cylinders or prisms many of them between two and three centimetres in length and as many millimetres in diameter. The ends are not pointed but neatly trimmed off by an oblique plane.

On closer examination these crystals prove to be thin walled tubes. The stalk attached to the bottle is solid for a few millimetres. Then a fine capillary appears, spreading out conically until the wall is about a half millimetre thick and then continuing as a uniform tube. The explanation is of course that within the tube the air is just saturated with phenol vapour while outside it is slightly supersaturated.

I do not remember meeting any published description of such crystals.

Science and Armaments.

WHAT Dr. Martin regrets, in his letter to NATURE of January 20, p. 82, is to me a consolation—to know that scientific men in our universities are still working for the safety of the realm, for across the Channel there are fierce black clouds and ominous rumblings of strife that seem almost beyond control.

Dr. Martin says: "So may the temple of science be kept free from echoes of human quarrels," and instances the sojourn of Davy and Faraday in Paris. Is the example fortunate? Davy was irresistibly attracted to Paris by reports of a detonator of fearful violence that had already deprived Dulong—its discoverer—of an eye and a finger. He spent much of his time there investigating another discovery of a manufacturer of salpetre, a substance not unknown to Ministers of Munitions.

It was this very journey that occasioned the human quarrel that we seek to forget when contemplating the lives of these two great priests of the temple of science.

JAMES WEIR FRENCH.

Anniesland, Glasgow, January 22.

The Opacity of an Ionised Gas.

IN a paper read before a joint meeting of the American Physical Society and the American Astronomical Society, in December, I pointed out that theoretically the absorption of radiation by free electrons should render an ionised gas highly opaque. The organised vibrational energy, due to the radiation, of the free electrons is transformed by collisions into disorganised thermal energy of translation. A tentative application of the methods of the well-known free electron theory of the optical properties of metals to conditions in an ionised gas gives the following equation for the volume opacity coefficient K. The quantity K is such that in distance z centimetres through the gas the intensity of the direct beam is reduced to e^{-Kz} of its initial value.

$$K=(6\cdot7\times10^{26})\frac{\lambda^2A^2ip^2}{T^7(1+i)^2}.$$

Here λ is the wave-length of the radiation in centimetres; i is the ratio of the number of free electrons to the number of atoms and ions; p is the gas pressure in atmospheres, including the partial pressure $ip/(1+i)$ of the free electrons; T is the absolute temperature, Centigrade; and A is the radius in centimetres of an atom or ion (assumed equal in size—a very rough approximation). This type of opacity increases as the square of the gas pressure, while the opacity due to general scattering increases only as the first power of the pressure. Even at fairly low pressures, however, the effect of absorption predominates in an ionised gas.

The above equation follows from the following assumed equation of motion of a free electron in an ionised gas through which radiation is passing:

$$m\frac{du}{dt}+2rmu=eX,$$

where m is the mass, and e the charge of an electron, and u is its component velocity in the direction of the electric vector X of the radiation. The term $2rmu$ represents a pseudo-frictional resistance due to collisions between electrons and atoms or ions; r is the number of such collisions per second per electron. The usual assumption is made that the velocity of an electron after colliding with an atom is independent of its velocity before collision; and collisions between electrons are neglected. (When the scattering of radiation by free electrons is dealt with a term involving $-d^2u/dt^2$ is added to the left-hand member of the equation.) The average rate at which energy is absorbed from the radiation by each electron is the average value of $\int eXu dt$; and, remembering that the intensity I of the radiation is $cX_0^2/8\pi$, where X_0 is the amplitude of X, K is easily found. The number of collisions per second per electron is taken as $\pi NA^2\sqrt{3RT/m}$, where N is the number of atoms and ions per unit volume, and R is the gas constant per molecule. This relation assumes equipartition of energy between free electrons and the other molecules in the gas.

The well-known experimental work of Dr. Anderson

at Mt. Wilson has shown that the opacity of the vapour of an exploded iron wire under certain conditions is such that light is cut off in a distance not greater than a few centimetres. Application of the above equation for K indicates that the absorption of radiant energy by the free electrons in the doubly ionised iron vapour produces an opacity of this order of magnitude. Thus, estimating T as 20,000 degrees absolute, i as 2, A as 5×10^{-8} cm. (doubtful), and $p/(1+i)$, the partial pressure of the iron ions, as 20 atmospheres (doubtful), K comes out as 1·7 for $\lambda=6\times10^{-5}$ cm. The electrical conductivity of the vapour theoretically is 1/1500th that of metallic copper.

Application of the equation for K to conditions in the outer regions of the sun, employing Saha's theory to calculate the ionisation as a function of the unknown gas pressure, makes it seem probable that at a depth in the sun where the pressure is as great as 0·01 atmosphere the ionised gas is sufficiently opaque to cut off radiation from farther down. This is, then, indicated as the approximate pressure in the solar photosphere; and pressures in the solar atmosphere are much lower. Thus the sharpness of the Fraunhofer lines may be explained. I hope soon to publish these results in detail. The astrophysical importance of the matter is obvious.

Naturally it will require a great deal of study to develop more than a rough theory of the opacity of an ionised gas. Radiation is selectively scattered by bound electrons; it is non-selectively scattered by free electrons; and it is absorbed by free electrons. The part played by bound electrons in absorbing radiation (that is, in transforming it to heat) seems at present far from understood. Prof. Eddington's recent discussion (*Observatory*, December 1922) of the absorption of radiation by quanta in the deep interior of stars perhaps opens a new line of attack on the general problem.

JOHN Q. STEWART.

The High Temperature of the Upper Atmosphere as an Explanation of Zones of Audibility.

THE work of Lindemann and Dobson on the theory of meteors,[1] with the remarkable conclusion that the temperature of the atmosphere at heights such as 80 kilometres is about the same as that near the earth's surface, will be far-reaching in its influence. May I be allowed to point out that one of the phenomena for which an explanation will probably be provided is the occurrence of zones of audibility and zones of silence, surrounding the scenes of great explosions.

If, as Lindemann and Dobson find, temperature increases rather rapidly at about 60 kilometres, then sound waves penetrating that region will be refracted back to earth, the comparatively rapid curvature of the sound rays making the phenomenon almost equivalent to reflection as is the case with the light rays which occasion mirage.

If we assume a sharp transition of temperature from 220° A. to 280° A. we find a refractive index for sound rays passing from the lower level to the upper of $\sqrt{280/220}$ or 1·13. Total reflection takes place with an angle of incidence 62°, and if the reflection is at 60 kilometres the minimum radius for the outer zone of audibility is $2\times60\times\tan 62°$ or 155 kilometres.

This rough estimate is of the right order of magnitude, as may be seen by comparison with the most recent example, the Oldbroek Explosion of October 28, 1922, for which the corresponding limit is stated to have been "about 180 or 200 km." (NATURE, January 6, p. 33).

There should be no great difficulty in adapting the theories worked out by von dem Borne and de Quervain to the new hypothesis. The drift of meteor trails shows that there is considerable horizontal motion of the atmosphere at such heights as 60 kilometres, and this motion will have to be taken into account. It is not unlikely that monsoonal changes in the upper winds produce the seasonal variation in the direction of audibility which was so noticeable during the war. The number of known observations of meteor trails is too small (*cf. Meteorological Magazine*, vol. 56, p. 292, 1921) to throw any light on this question.

Further progress in our knowledge of the temperature of the outer atmosphere and of its motion would be made if Prof. Goddard could send up his rockets. The times of passage of the sound waves from the bursting rockets would give immediate information as to the temperature of the air. Perhaps it would be more practicable to use a "Big Bertha" to send up a bursting shell. Mr. Denning could say, no doubt, whether there are any instances in which the disruption of a meteor has been heard and the time interval between sight and sound has been recorded.

With regard to the theory suggested by Lindemann and Dobson in explanation of the high temperature of the outer atmosphere, it should be pointed out that the atmosphere is only exposed to solar radiation during the day-time. It would seem that the equation by which the authors determine the steady temperature should be modified considerably. Annual variation in the temperature of these outer layers of the atmosphere is to be anticipated; it is not unlikely that examination of the statistics regarding meteors will reveal it. According to the theory meteors should reach much lower levels in winter than in summer.

Fixation of Nitrogen by Plants.

IN NATURE of January 20, p. 95, reference is made to an announcement in *Science* by Lipman and Taylor that they have proved conclusively the fixation of atmospheric nitrogen by the wheat plant. Should the detailed evidence, when available, show that their claim is well founded, it should not be forgotten that similar results on other plants were obtained in this country some little time ago by the late Prof. Benjamin Moore and his co-workers. In two communications to the Royal Society (Proc. Roy. Soc., B, vols. 91 and 92, 1920), he argues strongly in favour of such fixation, supporting his views by convincing experimental proof on both fresh-water and marine algæ. The work was incorporated in his book "Biochemistry" (1921), and in the Hugo Müller memorial lecture delivered before the Chemical Society in June of that year—one of his last public utterances—he reiterates in the strongest language his belief, founded upon no inconsiderable amount of experimental work, "that both the lower and higher plants do build up nitrites and nitrates and form organic nitrogenous compounds from the free nitrogen of the atmosphere."

I may say that in their article in *Science* Messrs. Lipman and Taylor give references to Moore's work as to that of other previous observers.

Insulin, Diabetes, and Rewards for Discoveries.

By Sir W. M. BAYLISS, F.R.S.

A NUMBER of problems, some of great scientific interest, others of practical importance in various ways, have been brought to notice by the somewhat sensational statements in the daily press relating to the Canadian treatment of diabetes by a preparation extracted from the pancreas and known as "insulin" (see NATURE, November 25, p. 713; December 9, p. 774). In order to understand the state of affairs, it is necessary to review briefly our present knowledge of the physiological processes concerned with the utilisation of carbohydrate food. This will also serve to direct attention to gaps which need filling up, and the opportunities afforded by a trustworthy preparation of the hormone of the pancreatic "islets." If such a preparation shows itself to be of value in the treatment of diabetes in man, it is clear that difficulties of several kinds arise in the ensuring of an adequate commercial supply of an active product. We shall see further that the question of due rewards for discoveries which involve the cure of disease arises in the present case in an acute form.

If we look at tables drawn up to indicate a reasonable proportion between the constituents of a normal diet, we notice how large a part of the total energy required is supplied by carbohydrate. In that of the Royal Society Food Committee, for example, more than 65 per cent. is from this source. The justification is given by the fact that evidence of various kinds shows that the material from which muscle directly derives the energy for its activity in normal conditions is glucose. This is burned up with consumption of oxygen, while the products finally leave the body as carbon dioxide and water. Since measurements of the "Respiratory Quotient" in muscular work form a part of the evidence and are of importance in judging the properties of insulin, a word may be useful here as to the meaning of this number. If glucose is burned in the ordinary way in air, and the amount of oxygen consumed and of carbon dioxide and water produced is determined, the volume of carbon dioxide is found to be equal to that of the oxygen used. This is of course due to the fact that carbohydrate contains sufficient oxygen in its molecule to oxidise the hydrogen. Fat or protein, on the other hand, requires more oxygen, to burn part of the hydrogen as well as the carbon. The respiratory quotient expresses the ratio of the volume of the carbon dioxide produced to that of the oxygen consumed, so that if carbohydrate alone is burned, the value is unity, and it decreases in proportion to the amount of the fat or protein burned. If it rises, due attention being paid to absence of retention of carbon dioxide, we are justified in concluding that more carbohydrate is being oxidised.

Glucose is also known to be consumed in other organs—the secreting glands, for example—and probably in the tissues generally. It is supplied by the blood, although only present therein in very low concentration, about 0·1 to 0·15 per cent. Being a crystalloid and filtering through the glomeruli of the kidney, a large quantity would be lost were it not that as this filtrate flows along the renal tubules, the glucose is almost entirely reabsorbed, along with other constituents of value. If, however, the concentration of sugar in the blood rises above the normal value (hyperglycæmia), owing to a large amount of carbohydrate in the food, or an incapacity on the part of the tissues to consume it to the proper degree, then the absorptive power of the kidney is insufficient, and sugar appears in the urine (glycosuria). The glycosuria resulting from excess of blood-sugar owing to diet is in itself harmless; glucose is often added to gum-saline for intravenous injection in cases of traumatic shock. When glycosuria, on the other hand, is due to failure to consume glucose, we have the morbid state known as diabetes mellitus, in which there are involved other consequences of this defect, themselves giving rise to serious symptoms.

Since the supply of sugar from the digestive canal is intermittent and in excess of the immediate demand, while this demand is constant, it is clear that some means of storage is needed. This is provided by the liver, which deposits glucose in its cells in the form of the insoluble glycogen. From this store it is released as required. The muscular tissues, especially that of the heart, are also able to store glycogen to some extent. Now in diabetes it is found that the liver has lost this power, although the muscles retain it. It is not obvious why this loss of storage power in the liver should be connected with failure of the tissues generally to consume glucose, but so it is; and there is another rather remarkable fact. If the food given to a diabetic animal is devoid of carbohydrate, glucose is produced from certain amino-acid components of proteins, although it is not utilised, and escapes in the urine. It may be that the consumption of glucose is never completely absent in diabetes, but is dependent on a high concentration in the blood. This minimal consumption being absolutely essential to life, it is provided from protein, if no other supply is available. Hence the great wasting of body substance present in diabetes.

In the year 1889, a paper by Von Mering and Minkovski was published, in which it was shown that if the pancreas was removed from dogs, a condition like that of diabetes was produced. They found further that if a small piece of the pancreas had previously been grafted under the skin, removal of the rest of the pancreas was ineffective until this graft was also removed. It was also found that ligature of the ducts of the pancreas did not produce diabetes. These results pointed clearly to an internal secretion from the pancreas as being necessary for the utilisation of sugar. It was found that the residue of pancreatic tissue left in both the cases referred to consisted of the structures known as "Islets of Langerhans," and it was advocated by Sharpey Schafer that these organs are responsible for the internal secretion. Further evidence confirmed this view, although there are still some differences of opinion as to the independence of the islet tissue and the ordinary secreting tissues. The discovery of Diamare that in many teleostean fishes the islet tissue exists in organs separate from the pancreas is important evidence that this tissue is not in the adult formed from the pancreatic cells. In Lophius, according to Diamare, these masses of islet tissue may be as

large as peas. But, for some reason or other, extracts of the pancreas have only occasionally been found to have any influence when given to diabetic animals. The active constituent is destroyed by some other substance, possibly trypsin, contained in such extracts.

Since the cells which produce trypsin degenerate after tying the ducts, it occurred to Dr. Banting, rather more than a year ago, that extracts of such organs might contain the active principle sought for, free from destruction. Dr. Banting was then in medical practice at London, Ontario, but gave up his practice and went to Prof. Macleod's laboratory at Toronto to make the necessary experiments on animals. Here he was joined by Mr. Best, an assistant in the laboratory, by Prof. Macleod himself, and at a later date by Dr. Collip and others. The experiments were successful. In another way it was found possible to prepare active extracts. It had been noticed that the presence of a fœtus protects the mother. The islet tissue, as it appears, begins to be functional at an earlier date than the secreting cells, so that by taking the pancreas of a fœtal calf at the appropriate age, the destructive agent was absent. But it was clear that these methods could only afford a small supply. Hence attempts were made to discover a means of preparation from the ordinary ox pancreas. Dr. Collip was finally successfully by making use of alcohol. The active principle, which it is proposed to call "insulin," is soluble in alcohol of a strength such as to precipitate enzymes, proteins, and probably other substances, although, like secretin, it is insoluble in absolute alcohol. This latter fact gives opportunity for further purification from lipoid. It is finally obtained in solution in physiological saline, suitable for subcutaneous injection. The absence of protein is necessary for clinical use, because of the possibility of anaphylactic shock, if the injections were omitted for a time and then resumed.

Passing next to the properties of insulin, it was found that if injected subcutaneously into animals made diabetic by removal of the pancreas, or indeed hyperglycæmic in any way, the sugar content of the blood was reduced and the glycosuria abolished. Moreover, a very interesting fact was discovered. The blood sugar can be reduced in normal animals by insulin, but if it falls below a certain level (about 0·045 per cent. in rabbits), nervous symptoms come on, and the animal may die in convulsions. These symptoms are at once removed by injection of glucose. Thus the normal activity of the central nervous system depends on the presence of a sufficient concentration of sugar in the blood. It is probable, therefore, that sugar is burned in the brain, and possibilities of investigating the energy value of the cerebral processes associated with mental activity open before us. The fact, however, causes a difficulty in the clinical use of insulin. If too large a dose be given, or it be absorbed too rapidly, nervous symptoms make their appearance. Fortunately, they are unmistakable by the patient, who can at once have recourse to the sugar basin.

Another important action of insulin is to reduce or abolish the presence of acetone and its derivatives in the blood and urine—a characteristic sign of the diabetic state. These compounds have a toxic action on the nervous system, finally leading to coma and death. They are the result of incomplete combustion of fat, and are present whenever insufficient sugar is being oxidised—in carbohydrate starvation as well as in diabetes. It is an interesting fact that neither fat nor protein can be properly utilised without carbohydrate. The oxidation of the former appears to be a kind of "coupled reaction" with that of sugar, and we therefore ask what is the common component? Pyruvic acid or aldehyde, as a stage in the oxidation of both, has been suggested. Vahlen put forward the view some years ago that the function of the pancreatic hormone was to convert glucose into a simpler compound more easily oxidised. These possibilities may be accessible to experiment *in vitro* by the use of concentrated solutions of insulin. According to some recent work by Winter and Smith in the Biochemical Laboratory at Cambridge, it seems that γ-glucose, the reactive ethylene-oxide form of glucose, is the first stage, insulin acting as the activator of some enzyme in the tissues. In the normal state, the blood sugar is in the γ-form, presumably not in diabetes.

The failure to make use of protein in the absence of concurrent oxidation of glucose may have some bearing on another characteristic of the diabetic state —the imperfect healing of wounds. It is pointed out by Dr. Formiguera in the *British Medical Journal* of December 9 last that insulin will be of much value in making possible the performance of necessary operations in the diabetic—a matter otherwise not to be done. Prof. Starling has suggested that its use may also make it feasible to transplant grafts of fœtal pancreas into such cases. Although the work of Leo Loeb has made it clear that tissues from another individual, unless a very closely related one, degenerate sooner or later when transplanted, embryonic tissues are not so extremely individualised, and the experiment is worth trial.

Insulin confers on the diabetic liver the power of storing glycogen.

Since the capacity of oxidising glucose is deficient in the diabetic animal, an injection of glucose does not raise the respiratory quotient; whereas if insulin be given at the same time this happens. Thus we have the proof that glucose is actually burned and not caused to disappear in some other way. It is further shown by Hepburn and Latchford that the excised heart of the rabbit consumes more glucose if insulin be added to the perfusing solution. Unfortunately, it was not shown that the respiratory quotient was raised, and the authors have overlooked the fact that Starling and Evans in 1914 found in some cases that the respiratory quotient of the diabetic heart was raised by the addition to the blood of an acid extract of the pancreas. It may be remarked that trypsin being inactive in acid solution, it was thought to avoid destruction of the hormone in this way. Indeed, although it is actually destroyed in an alkaline solution of trypsin, it is not certain whether it may not be oxidised, or destroyed by some agent other than trypsin itself.

Insulin, given to diabetic patients by subcutaneous injection, is found to have the same effects as in animals, together with an unmistakable improvement in condition. Apart from its relieving the serious

symptoms actually present, it is greatly welcomed in place of the "starvation" treatment of Allen, the only other treatment of value. But it is evident from what has been said above that there is much to be found out in respect to its practical use. Since only a small dose can be given at one time, because of the nervous effects of too great a reduction of the blood sugar, and since the effect only lasts about twelve hours, it is clear that two subcutaneous injections per day are necessary. Although it may be said that people addicted to morphine or cocaine use the process as often as this, the difficulty is not to be overlooked. If the morbid condition of the pancreas has not advanced too far, it may turn out that insulin "relieves strain," as it were, so that the normal state may ultimately be restored. But this has not yet been ascertained. Destruction by the pancreatic juice makes insulin ineffective if taken by the mouth. Perhaps some method may be found by which it may be caused to be absorbed by the stomach before being destroyed. The supply on a large scale involves problems, moreover, which do not arise in the small scale operations of the laboratory.

Here we meet with the knotty question brought into prominence by the action of the University of Toronto in taking out a patent and offering the rights in this country to the Medical Research Council. According to the statement published by this body in the *Times* of November 17 last, the gift has been accepted, and application for a patent in this country has been made by the University of Toronto. It may well be that this University does not altogether realise the fact that there is a strong feeling here against patenting products of value in the cure of the disease, so that the action of the Medical Research Council is viewed with some degree of misgiving. It is plain that the more work there is done both on the properties and on the modes of preparation of pancreatic extracts the better. While it would be absurd to suggest that the Medical Research Council has any desire whatever to obstruct such research, the necessity for any laboratory being unable to do this except by arrangement with the patentees does not seem desirable. The best modes of large scale preparation would surely be discovered in the shortest time by ensuring that any firms having the necessary plant may be free to make any experiments that may seem promising. Every credit must be given to the Medical Research Council in its desire to protect the public from the results of putting on the open market preparations of unknown potency, some inactive, others too powerful. The words used by the Council may be quoted: "The intention of the Council is to promote, in the light of recent experience in Canada, and of such new knowledge as research will gain, whatever enterprise or organisation is best fitted for securing the earliest production of the Insulin extract under proper conditions of safety and control, and so to facilitate, with the least possible delay, a thorough and scientific trial of the new treatment in this country."

We may ask, would not the best way to effect these objects be to announce that the Medical Research Council were prepared to test and certify preparations sent to them? It may be objected that a large amount of work would be involved in the testing of numerous small batches, since the only method known as yet requires the use of rabbits. Here is room for investigation, but in the meantime the difficulty might be avoided by refusing to certify any but large batches. If the Medical Research Council were satisfied that a particular firm had the facilities for making such tests themselves, they might agree to accept this firm's own tests, it being always understood that any preparation was liable to control, and a failure to confirm the makers' statement would be ruinous to their reputation.

But there is a further reason that seems to the writer to make such a course the wiser one. The well-meant gift of Toronto University has unquestionably put the Medical Research Council in a somewhat awkward position. In view of the facts referred to in the earlier part of this article, namely, that active extracts have already been made in this country and methods published, it is clear that any general patent could not be upheld. If Collip's special process were patented, it would be open to a maker to vary the solvent, say by using acetone. The writer has found that acetone is less injurious to enzymes than alcohol is, and it might be worth testing for the purpose of preparing insulin. Even if a patent were granted, it would be a very costly and troublesome process to prosecute for infringement, whereas failure to satisfy the Medical Research Council's test would prevent the sale of any worthless preparation. It is indeed quite possible that the objection taken to the apparent policy of this Council is based on a misunderstanding, and that it will turn out that this policy is essentially what is advocated here.

There is another aspect of the matter which has been brought to notice somewhat acutely by the special circumstances of this case. Whatever may be the object of the University of Toronto, there can be no manner of doubt that those who have given time to, and been put to pecuniary loss by work for, the benefit of humanity ought not to suffer. I am informed that Dr. Banting gave up his medical practice to devote his whole time to the research. It may perhaps be objected that if he returns to practice with the reputation gained, large numbers of patients will come to him. But this does not affect the principle. If discoveries in the medical sciences are not to be patented, the question arises as to how their discoverers are to be rewarded. It is absurd, as well as deterrent, to allow the mental capacities which applied to industry would have brought a fortune, to go unrewarded in science. Men of science do not expect fortunes, but freedom from worry is essential for good work, and would well repay the comparatively small expenditure involved.

It may be remembered that about three years ago a combined committee of the British Science Guild and the British Medical Association considered the problem, and a deputation from them was sympathetically received by Mr. Balfour (now Lord Balfour). Subsequent needs for economy prevented any further action. Naturally, many difficulties as to points of detail arise, such as whether a single gift, on the lines of the Nobel prizes, or annual grants, would be the better method. Again, it may be said that a particular discovery is necessarily based on the work of many predecessors. Or a man's work may not lead at once

to any discovery of practical value, although the foundations of future valuable discoveries may be laid. There is much to be said in favour of rewards for good work done, as well as for providing means for doing it. It would probably be found in practice that the difficulties are not so great as might appear. It may be suggested that funds might be voted to the Medical Research Council and to the Department of Scientific and Industrial Research for the special purpose indicated.

The Identity of Geber.

By E. J. HOLMYARD, Clifton College.

IT is generally agreed that the masterpieces of medieval chemical literature are the "Investigation of Perfection," the "Sum of Perfection," the "Invention of Verity," and the "Book of Furnaces," ascribed to "Geber, the Most Famous Arabian Prince and Philosopher." They are written in clear and definite language and are free from the enigmas and allegories which disfigure so large a proportion of alchemical books, and they contain much precise chemical information. The earliest Latin manuscripts of these works appear to be of the late thirteenth century, and they profess to be translations from the Arabic of Jābir ibn Ḥaiyān, who lived in the eighth century A.D.

The Arabic origin of Geber's works was universally accepted until the middle of the nineteenth century, when Kopp first expressed doubts as to their authenticity. Kopp, however, knew no Arabic and was not acquainted with any Arabic works of Jābir, so that his suggestion was merely tentative. Additional evidence was secured by Berthelot, who caused translations to be made of a few Arabic manuscripts containing works ascribed to Jābir ibn Ḥaiyān, and compared these translations with the Latin works mentioned above. He came to the conclusion that Geber's works were European forgeries of the thirteenth century and could certainly not be regarded as translations of works of Jābir ibn Ḥaiyān. Up to the present no one has challenged Berthelot's conclusion, and all historians of chemistry have followed him blindly, without critical examination of the material upon which his conclusion was based. I hope to show in the present article that there is a good deal more in the problem than Berthelot seemed to realise, and, while not claiming to have proved definitely that Geber and Jābir are identical, I believe that the evidence now accumulated renders this identity extremely probable.

It is necessary in the first place to consider the data which Berthelot had at his disposal, and to estimate their value; and secondly, to enumerate the definite points in his argument. A fact of prime importance is that Berthelot was completely ignorant of Arabic and was therefore not in a position to draw conclusions from considerations of style—yet this is what he continually attempted to do. This habit of Berthelot's has been severely criticised by von Lippmann ("Entstehung und Ausbreitung der Alchemie," Berlin, 1919), and I need not enlarge upon it here.

Berthelot's acquaintance with Arabic alchemy was limited in two senses, for, in addition to his want of knowledge of the language, he knew even in translation only thirteen small works, nine of which are attributed to Jābir. While, therefore, one has the greatest admiration for Berthelot's invaluable pioneer work, one is justified in holding that the foundation of the edifice which he reared is somewhat insecure. The more I investigate the subject the more do I feel, with Berthelot's countryman Prof. E. Blochet, that "il faudrait des années d'un labeur ininterrompu pour tirer des manuscrits la doctrine arabe de la chimie."[1]

According to the "Kitāb al-Fihrist," a Muslim encyclopædia of the tenth century A.D., Jābir wrote at least five hundred books, some large and some small. About fifty of these are known to exist, and I have no doubt that many others could be found by diligent search. A study of the extant manuscripts shows that Jābir was very catholic in his learning—he was at once philosopher, physician, mystic, and chemist. It so happens that Berthelot came upon some of the more mystical of Jābir's works, and was therefore led to a wrong conclusion as to his attainments in chemistry.

To come now to the definite points in Berthelot's argument. It will be convenient to give these so far as possible in his own words ("La Chimie au moyen âge," tome i.).

1. La première et la plus essentielle, c'est que le texte arabe renferme certaines des doctrines précises sur la constitution des métaux, que nous trouvons dans les textes latins réputés traduits de l'arabe et attribués [à Geber]; tandis qu'une autre partie de ces doctrines manque complètement dans les traités arabes et paraît dès lors appartenir à une période plus moderne. Ainsi la doctrine des qualités occultes, opposée aux qualités apparentes, est formellement exposée dans les textes arabes de Djâber [Jābir]. . . . Au contraire, aucune allusion n'est faite dans les textes arabes précédents à la théorie de la génération des métaux par le soufre et le mercure.

2. On ne rencontre . . . dans les œuvres arabes de Djâber, de recette précise pour la préparation des métaux, ou des sels, ou de quelque autre substance.

3. Dans ces traités arabes, le langage est vague et allégorique.

4. Aucune doctrine ou fait précis n'est énoncé, aucun personnage n'est cité.

5. (No direct quotation of Geber is made by Albertus Magnus or Vincent de Beauvais, the presumption being that the Latin works of Geber were therefore not known to these two alchemists.)

6. La *Summa* ne contient . . . aucune des formules musulmanes . . . dont [Jābir] est prodigue.

7. (The *Summa* contains an account of the arguments of those who denied the possibility of transmutation. Of this "on n'en trouve aucune trace dans les opuscules arabes de Djâber.")

8. (The style of the *Summa* recalls that of the Schoolmen.)

9. L'auteur (of the Latin works) dit que, d'après lui, il existe, en réalité, trois principes naturels des métaux: le soufre, l'arsenic qui lui est congénère,

[1] Private communication to the author.

et le mercure. Ce sont là, en réalité, des théories nouvelles, postérieures à celles d'Avicenne.

10. (All the *Summa*) "est d'une fermeté de pensée et d'expression, inconnue aux auteurs antérieurs, notamment au Djâber arabe."

11. There is no mention in the Arabic work of nitric acid, *aqua regia*, or silver nitrate, all of which are described in the Latin works.

It will be observed that all these arguments are negative ones, and rest upon the difference between the Latin works and the Arabic opuscules of Jābir known to Berthelot. Up to the present I have not found any Arabic works which can be considered as the originals of the Latin treatises, but that there is much to be said against Berthelot's conclusions will be apparent from the following remarks, which I have numbered to correspond with the preceding quotations.

1. Jābir enunciates the sulphur-mercury theory of metals in the first book of his "One Hundred and Twelve Books" (quoted by Al-Jildakī in vol. i. of the "Nihāyat aṭ-Ṭalab"). He says very definitely that "the seven fusible bodies are composed of mercury and sulphur." Compare this with chap. ii. of the "Investigation of Perfection": "All metallick bodies are compounded of argentvive and sulphur." This is expanded in the "Book of Properties," section 12 (B.M. manuscript), where Jābir advances the theory that all minerals, whether metallic or not, are composed of mercury, sulphur, gold, and sal-ammoniac.

2. Jābir can be quite definite when he likes; the three preparations given below are taken from the "Book of Properties."

(*a*) Section 36. "Take a pound of litharge, powder it well and heat it gently with four pounds of wine vinegar until the latter is reduced to half its original volume. Then take a pound of good *qalī* (crude sodium carbonate) and heat it with four pounds of fresh water until the volume of the latter is halved. Filter the two solutions until they are quite clear and then gradually add the solution of *qalī* to that of the litharge. A white substance is formed which settles to the bottom. Pour off the supernatant water and leave the residue to dry. It will become a salt as white as snow." (*b*) Section 38. "Take a pound of litharge and a quarter of a pound of soda, and powder each well. Then mix them together and make them up into a paste with oil and heat in a descensory. (The metal) will descend pure and white." (*c*) Section 36. "To convert mercury into a red solid. Take a round glass vessel and pour a convenient quantity of mercury into it. Then take a Syrian earthenware vessel and in it put a little powdered yellow sulphur. Place the glass vessel on the sulphur and pack it round with more sulphur up to the brim. Place the apparatus in the furnace for a night, over a gentle fire . . . after having closed the mouth of the earthenware pot. Now take it out and you will find that the mercury has been converted into a hard red stone of the colour of blood. . . . It is the substance which men of science call cinnabar."

3. That many of Jābir's books are couched in allegorical language no one will deny, but in others there is scarcely any trace of allegory (*e.g.*, the "Book of Properties") and Jābir is quite capable of sustaining a closely reasoned argument. Lack of space prevents me from illustrating this point as fully as I could wish, but I may perhaps refer to the "Book of Balances," where he says, "It must be taken as an absolutely rigorous principle that any proposition which is not supported by proofs is nothing more than an assertion which may be true or may be false. It is only when a man brings proofs of his assertion that we say, your proposition is true." Similarly, he is at pains in the "Book of Properties" to make it clear that he is describing his personal experiences; "we have described only that which we ourselves have seen, and not that which was told us or what we heard or read." Jābir is very precise, again, in his "Book of Definitions."

4. Berthelot's fourth argument is sufficiently answered by the evidence I have brought forward in 1, 2, and 3. In his "Book of the Divine Science," Jābir refers to Pythagoras and Plato, and defines chemistry as "that branch of natural science which investigates the method of formation of the fusible bodies" (*i.e.* the metals). His views on the structure of cinnabar, given in the same book, are so precise, and refute Berthelot's charge of vagueness so well, that I cannot refrain from quoting them here.

"When mercury and sulphur combine to form one single substance it has been thought that they have essentially changed and that an entirely new substance is formed. The fact is otherwise, however. Both the mercury and the sulphur retain their own natures —all that has happened is that their parts have become attenuated and in close approximation to one another, so that to the eye the product appears uniform. But if one could find an apparatus to separate the particles of one sort from those of the other, it would be apparent that each of them has remained in its own permanent natural form and has not been transmuted or changed. We say, indeed, that such transmutation is not possible for natural philosophers."

5. If Albertus Magnus and Vincent de Beauvais knew no Arabic, and if the *Summa, etc.*, (supposing that they were originally Arabic) had not yet been translated into Latin, the absence of mention would be explained. In any case, the argument *a silentio* is always unsatisfactory.

6. It is here that Berthelot's ignorance of Arabic has led him astray. As a matter of fact, the *Summa* is full of Arabic phrases and turns of thought, and so are the other Latin works. It is obvious that a full discussion of this point would require far more space than is available here, and I hope to treat of it elsewhere. I will, however, quote one or two passages of Russell's English translation of Geber which are of unmistakable Arabic origin. "Our Art is reserved in the Divine Will of God and is given to, or withheld from, whom he will, who is Glorious, Sublime, and full of all Justice and Goodness." ". . . transmute with firm transmutation" (a well-known construction in Arabic). "This Divine Art, which is both necessary and known." "Now let the high God of Nature, blessed and glorious, be praised, who hath revealed to us the Series of all Medicines." "We have dispersed the special things pertinent to this Praxis, in diverse Volumes" (often said by Jābir). "Gold Obrizon" (dhahab ibrīz). "One part tingeth infinite parts of Mercury into most high Sol, more noble than any natural Gold." "Festination is from the Devil's part."

7. So far, I have not found in Jābir any mention of the arguments against the possibility of transmutation

to which Berthelot refers, but Jābir is never tired of pointing out the errors of other chemists and insisting upon the superiority of his own theories and methods. He even curses them in the manner of the Latin works.

8. The style of the Latin works does indeed resemble that of the Schoolmen, but so does that of many of the Arabic works of Jābir. I would refer especially to the first twelve sections of the "Book of Properties," and to the "Book of Definitions."

9. Arsenic as one of the principles of metallic bodies is referred to by Jābir in Book I. of the "Hundred and Twelve Books" (quoted by Al-Jildakī in vol. ii. of the "Nihāyat aṭ-Ṭalab"). "Arsenic" here refers of course to the arsenic sulphides, realgar and orpiment. It will be noticed that the Latin Geber does not insist upon the necessity of arsenic; in this he is in agreement with Jābir. Both agree in regarding the prime constituents of metals to be sulphur and mercury.

10. I have explained Berthelot's insistence on the difference in style between the Latin works and the Arabic treatises as due to the fact that Berthelot was unlucky in his choice of the latter.

11. I cannot say whether the Arabic Jābir definitely mentions nitric acid, *aqua regia*, and silver nitrate. It is unfortunate that the pages referring to solutive waters are missing from the British Museum MS. of the "Book of Properties," especially as I believe this MS. to be unique. Al-Jildakī mentions a "solutive water" (*ma' al-ḥilāl*) which was used to dissolve out silver from a gold-silver alloy; I presume this must have been nitric acid. Al-Jildakī, however, lived after the date of the earliest MSS. of Geber's works.

I ought to say that I have hitherto examined by no means all of the available material, and that in the present article I have only very roughly sketched out the case for the identity of Geber and Jābir. I hope to deal with the subject much more fully in the future, but the question of the identity of Geber is so important for the history of chemistry that it seemed desirable to publish a preliminary account of some of my conclusions.

The Alleged Discovery of the Virus of Epidemic Influenza.

THE recent report in the daily press that the cause of influenza had been discovered by Drs. P. K. Olitsky and F. L. Gates, of the Rockefeller Institute, N.Y., might lead the layman to believe that the problem was solved. There is no published evidence to show that this is correct. The facts are briefly these. Influenza is the greatest pandemic disease known and may be traced to the most remote periods of which we have historic data. One of its great outbursts (1889–1890) coincided with the bacteriological epoch in science, and by means of the technique devised by Robert Koch, one of his assistants, R. Pfeiffer, distinguished by the accuracy of all his work, isolated (1892) a small rod-shaped microbe since universally called *Bacillus influenzæ*. This microbe, not easy to cultivate, was missed by all the investigators before Pfeiffer, but his work was subsequently regarded as correct.

In succeeding years influenza as an epidemic disappeared and little was heard of Pfeiffer's bacillus in bacteriological literature. In 1918, under the title of Spanish influenza, the disease again appeared, and sweeping over the inhabited world like a prairie fire, caused immense morbidity and mortality everywhere. The microscopes of bacteriologists were riveted on the disease processes of the plague. The results of tried investigators varied, but with prolonged experience and suitable methods the bacillus of Pfeiffer was found almost everywhere in cases of the disease. Dissentient voices were, however, raised here and there, partly owing to inability to find the bacillus, partly owing to the fact that when found it was difficult to prove its causal relation to influenza, as animals are by no means so susceptible to the disease as man.

It was believed and stated, in fact, that Pfeiffer's bacillus was not and could not be the cause of influenza, which was to be sought in some hitherto unknown or unrecognised agent. Among those who held this view must be mentioned Gibson Bowman and Connor, who, attached to the B.E.F. in France, published statements (1919) to the effect that influenzal secretions which had been forced through bacterial-proof filters, gave rise in monkeys, rabbits, mice, and guineapigs to a disease closely resembling that of human influenza. They claimed to have transmitted the disease from animal to animal in series. They believed that the virus was a "filter passer." Independently, Bradford, Bashford, and Wilson made similar claims, which they afterwards withdrew. Following the same lines, Maitland, Cowan, and Detweiler of Toronto recorded entirely negative results and directed attention to grave errors which might arise in interpreting results believed to be positive. What were described as typical effects by the supporters of the filter-passing-virus theory were shown by the Canadians to occur in animals that had never been inoculated at all but which had been intentionally killed. This fact has since been abundantly confirmed by Branham (1922) and shown by her to occur when death is brought about by a blow on the neck. It is along the same route that the Rockefeller investigators have proceeded, from whose work it is now claimed that the etiology of influenza is settled, and it is claimed that the virus is a body called by them *Bacillus pneumosintes* (σίντης, injurer or devastator—from its supposed deleterious effect on the lungs).

In the last two years Olitsky and Gates have published a long series of papers in the *Journal of Experimental Medicine*, giving the results of their inquiries. Their claims are based on the following statements. (1) Influenzal throat secretions diluted and filtered through Berkefeld filters produce symptoms which cannot be produced by similar filtrates from normal persons. The symptoms—in rabbits—are fever, conjunctivitis, and a diminution in the number of leucocytes in the blood, a symptom which is very characteristic of the influenza disease in man. None of the animals died of the experimental disease, but on being killed, the lungs were found mottled and hæmorrhagic. (2) The lesions in the lungs are said to be transmissible in series. (3) Although none of the experimental animals died, they are stated to have been rendered

more susceptible to a later infection by Pfeiffer's bacillus. (4) In the filtered washings peculiar "bacilloid" bodies were found measuring 0·15–0·30 μ in their long dimension. The nature of these bodies—at first uncertain—was ultimately believed to be micro-organismal. Hence the name *Bacillus pneumosintes*. (5) Inoculation of cultures of the so-called bacillus followed by injections of *B. influenzæ* resulted in the production of consolidation of the lungs with hæmorrhagic œdema and emphysema. (6) A certain degree of immunity is stated to follow injections of *B. pneumosintes*. (7) Inoculation of the bacterium is stated to evoke certain antibodies which are of a specific character. It may be stated that "cultures" of the microbe were obtained only on the highly complicated Smith-Noguchi medium, and especially under anaerobic conditions.

Before assuming that all these statements are correct it may be stated with respect to this microbe—if it is a microbe—that bacilloid and other like bodies indistinguishable in appearance from *B. pneumosintes* may occur in tubes of Noguchi's medium which has never been inoculated at all and nevertheless is sterile. The "bodies" appear to be due to some transformation of the colloid material of the medium itself. Such transformations may occur in tube after tube and give rise to the erroneous interpretation of successful transmission of the culture. Further, it is remarkable that the "microbe" does not kill the experimental animals, but that when they are killed afterwards they show changes admittedly indistinguishable from those seen in killed animals never inoculated. One great obstacle to the successful study of influenza would appear to be that animals are much less susceptible than man, and that as soon as the question of human inoculation is introduced, great difficulties ensue in excluding other sources of infection. Recently, Lister in South Africa, working on lines identical with those of Olitsky and Gates, has found, like them, *Bacillus pneumosintes* or similar "culture," but on inoculating such unheated cultures into human beings, 13 in number, he had only one success, a typical attack of uncomplicated influenza, after a nineteen-hours incubation period. It may be that the cause of influenza has been located in *B. pneumosintes*, but before this can be accepted by the bacteriological world in general it will be necessary to adduce many more cogent reasons than have been forthcoming so far. W. B.

Obituary.

Prof. Fritz Cohn.

FRITZ COHN, director of the Berlin Rechen-Institut, died on December 14 after an operation. He was born at Königsberg on May 12, 1866, and studied first at the Gymnasium and afterwards at the University there; after further study at the University of Berlin he was placed on the staff of the Königsberg Observatory in 1891 and remained there till 1909.

Cohn's work included a discussion of Bessel's observations between 1813 and 1819, and a determination of the declinations and proper motions of the stars used in the International Latitude stations. He published catalogues of the stars used for the Eros campaign in 1900–1, and of 4066 other stars observed with the self-registering micrometer of the Repsold transit circle.

In 1909, Cohn was appointed to the chair of theoretical astronomy at Berlin, and director of the Rechen-Institut. He took part in the Paris Conference of 1911 which arranged for combination of work between the national almanacks, to avoid needless duplication of labour. The time thus saved was devoted to investigations on the minor planets, and the Institut took the leading part in deducing their orbits, and in arranging plans for sharing the observing work among different observatories. He showed great skill in keeping up the necessary accuracy of computation without any waste of labour. He also carried on the Astronomisches Jahresbericht after the deaths of Wislicenus and Berberich, and left the MS. for the 1921 volume practically complete at the time of his death.

Cohn married a daughter of C. F. W. Peters, director of Königsberg Observatory, in 1898, and leaves a son and two daughters. A fuller account of his life and work is given by J. Peters in *Astr. Nach.* 5208.

Cohn was elected an associate of the Royal Astronomical Society in June 1913. A. C. D. C.

Mr. P. C. A. Stewart.

IT is with much regret that we record that Mr. P. Charteris A. Stewart, the well-known petroleum geologist and consultant to Viscount Cowdray's firm (Messrs. S. Pearson and Co.), met his death by drowning while bathing at Balandra Bay, Trinidad, B.W.I., during a recent short visit to the Islands.

For nearly twenty years Mr. Stewart has been connected with Messrs. Pearson's, and he had been closely associated with that firm in its important petroleum developments all over the world, more particularly in Mexico, Roumania, and Trinidad. Prior to this he held an appointment on the staff of the Geological Survey of Egypt.

Mr. Stewart's technical education was at the Royal School of Mines, where, in 1900 and 1901, he obtained diplomas in mining and metallurgy. Returning in 1904 he gained a further diploma in geology at the Royal College of Science in 1905. He was elected a fellow of the Geological Society of London in 1904, and was also a member of the Institution of Petroleum Technologists and the American Institute of Petroleum Geologists.

Mr. Stewart had travelled much, and by his wide experience and intimate knowledge of oilfield conditions in many countries he gradually built up a high reputation in his profession. His sound judgment in technical problems, backed by conscientious inquiry and skilful reasoning, made him an invaluable adviser to those whom he was privileged to serve. His death at the early age of forty-eight is a deplorable loss, one which will be keenly felt, not only by his colleagues, but also by his many friends, to whom he had endeared himself as a kindly, modest, and unselfish man.

H. B. M.

Current Topics and Events.

SINCE the publication of the letter "On the Missing Element of Atomic Number 72," by Dr. Coster and Prof. Hevesey, in NATURE of January 20, p. 79, it has been announced that Dr. Alexander Scott detected and separated the oxide several years ago. It appears that while examining in 1913 a specimen of titaniferous iron sand (75 per cent. Fe_3O_4, 25 per cent. TiO_2) from near Maketu in the North Island, New Zealand, Dr. Scott noticed that in the titanium dioxide separated in the ordinary methods of analysis there was always a small residue which resisted all attempts to get it into solution, either as sulphate, chloride, or nitrate. Neither would it go into solution after prolonged fusion with caustic soda. No trace of the many "rare earths" was found in the sand. The insoluble residue remaining after repeated and alternated fusions with sodium bisulphate and caustic soda was labelled "New Oxide" in 1918. Its properties and mode of occurrence indicated that it was an oxide of the titanium-zirconium group, and that it was the oxide of the missing element, of which the atomic number is 72. Some of its properties showed a resemblance to tantalum, its next neighbour, with the atomic number 73; but all traces of this element would be removed by the repeated fusions with caustic soda. As none of the ordinary salts were available for the purpose of determining the atomic weight, recourse was had to the double fluoride with potassium, which closely resembles those of titanium and zirconium. The rough determinations with material imperfectly purified for such a purpose indicated that the atomic weight of the element was between 1½ and 2 times that of zirconium (90·6). The oxide resulting from these determinations was of a cinnamon-brown colour, not white as was expected. We understand that Dr. Scott wrote on January 28 to Drs. Coster and Hevesey offering to send them specimens of his separated material to compare with their own, and received a reply from them on Saturday night last (February 3) saying they would be very glad to do so. On Monday Dr. Scott sent to them practically all his purified material, and not only he, but also all scientific men, must await with keen interest the result of the searching examination by means of the powerful appliances in their hands for spectral analysis by X-rays. In view of the source of his oxide and its association with much titanium oxide, Dr. Scott has suggested, as Oceanus was one of the Titans, that "Oceanium" would be a suitable name for the element. This name would also recall that the sand came from Oceania, of which New Zealand is one of the component parts.

THE Bakerian lecture of the Royal Society will be delivered on February 22 by G. I. Taylor and C. F. Elam on "The Distortion of an Aluminium Crystal during a Tensile Test."

THE Duke of Devonshire will open the new Botany (Plant Technology) Building of the Imperial College of Science and Technology, South Kensington, on Friday, February 16, at 3 o'clock.

AT the meeting of the Chemical Society to be held at the Institution of Mechanical Engineers (Storey's Gate), on Thursday, February 22, at 8 P.M., Principal J. C. Irvine will deliver a lecture entitled "Some Constitutional Problems of Carbohydrate Chemistry."

THE Murdoch Trust, Edinburgh, grants donations or pensions to indigent bachelors and widowers of upwards of fifty-five years of age who have done something to promote or help some branch of science. Particulars are obtainable from Messrs. J. and J. Turnbull, 58 Frederick Street, Edinburgh.

A SOCIAL evening of the Royal Society of Medicine will be held on Wednesday, February 28, beginning at 8.30. It will be devoted to the celebration of the centenary of Pasteur. At 9 o'clock the president, Sir William Hale-White, will deliver an address on "The Life and Work of Pasteur." This will be followed by an illustrated lecture by Dr. G. Monod on "Pasteur as an Artist."

ON Tuesday next, February 13, at 3 o'clock, Prof. A. C. Pearson will deliver the first of two lectures at the Royal Institution on Greek civilisation and to-day —(1) The beginnings of science, (2) Progress in the arts; on Thursday, February 15, Prof. B. Melvill Jones will begin a course of two lectures on recent experiments in aerial surveying; and on Saturday, February 17, Sir Ernest Rutherford will commence a course of six lectures on atomic projectiles and their properties. The Friday evening discourse on February 16 will be delivered by Prof. A. V. Hill on muscular exercise; and on February 23, by Prof. A. S. Eddington on the interior of a star.

NOTICE is given by the Royal Society of Medicine that the William Gibson research scholarship for medical women will be awarded in June next. The scholarship is of the value of 250*l.* for two years and is not necessarily for research, the selected scholar being free to travel. Full particulars will be sent on application to the Secretary of the Society, 1 Wimpole Street, W.1.

DURING the making of the new road between Dover and London numerous sarsen stones were found among the remains of the Lower Tertiary formations overlying the chalk near Maidstone. Two of these, selected by Mr. G. E. Dibley, were sent to the British Museum (Natural History), where they are now exhibited in the geological department close to the stratigraphical collection. They are remarkable for their botryoidal concretionary form.

A MEETING of national importance has been arranged by the British Science Guild to be held at the Mansion House, London, on Tuesday, February 27, at 3.30 P.M., to direct public attention to the importance of promoting efficiency and economy in industry, commerce and all Imperial affairs by the progressive use of science and scientific method. The Right Hon. the Lord Mayor will preside, and will be supported by the Right Hon. Lord Askwith,

president of the Guild. The speakers will include Sir Joseph Thomson (Master of Trinity College, Cambridge), Sir Robert A. Hadfield, Bart. (Vice-President of the Federation of British Industries), and the Right Hon. Sir Joseph Cook, G.C.M.G. (High Commissioner for Australia). Tickets may be obtained from the Secretary, British Science Guild, 6 John Street, Adelphi, London, W.C.2.

THE president and council of the Royal Society have appointed Prof. E. H. Starling first Foulerton professor in accordance with the terms of the bequest of Miss Lucy Foulerton, who left the residue of her estate to the Royal Society. The duties of the professor are to conduct such original researches in medicine or the contributory sciences as shall be calculated to promote the discovery of the causes of disease and the relief of human suffering. Prof. Starling's work will be carried out at University College, London. Dr. H. W. C. Vines, fellow of Christ's College, Cambridge, has been appointed to a Foulerton research studentship, the duties being to conduct researches in medicine or the contributory sciences. Dr. Vines is carrying on his researches in the Cambridge Medical School.

AT the annual general meeting of the Association of Economic Biologists held on Friday, January 26, the following officers and council for the year 1923 were elected: *President*: Prof. E. B. Poulton. *Vice-Presidents*: Prof. V. H. Blackman and Sir John Russell. *Treasurer*: Dr. A. D. Imms. *Secretaries*: (General and Botanical): Dr. W. B. Brierley; (Zoological) Dr. J. Waterston. *Editors*: (Botany) Dr. W. B. Brierley; (Zoology) Mr. D. Ward Cutler. *Council*: Dr. W. F. Bewley, Prof. V. H. Blackman, Mr. F. T. Brooks, Mr. A. B. Bruce, Dr. E. J. Butler, Dr. J. W. Munro, Sir John Russell, Prof. J. H. Priestley, Prof. J. H. Ashworth, Dr. T. Goodey, Mr. A. D. Cotton, and Mr. W. E. Hiley.

A JOINT meeting of the Society of Public Analysts and the Nottingham Section of the Society of Chemical Industry was held at Nottingham on January 17 for the discussion of methods of estimating arsenic. The chair was taken by Mr. Burford, chairman of the Nottingham section, and the discussion was opened by Mr. A. Chaston Chapman, who described his experience during the last twenty-five years with the zinc-acid process, and gave an outline of his procedure, more particularly in the use of cadmium to render the zinc sensitive. He was followed by Mr. Wilkie, secretary of the Nottingham section, who demonstrated the use of his electrolytic method of estimating arsenic, in which the reversibility of the reaction was prevented. Dr. Monier-Williams showed an electrolytic Marsh apparatus modified from that in use in the Government laboratory. Mr. H. Droop Richmond attributed the want of sensitiveness of the zinc in the zinc-acid method to the presence of iron, and Mr. J. Webster described an experiment indicating that the total amount of arsenic in a large organ such as the liver was correctly estimated by multiplying the amount found in the Marsh test by a factor.

THE New York correspondent of the *Times* states that an earthquake of considerable violence was recorded in the United States on February 4. A sea wave 12 feet high is reported at Hilo Harbour, Hawaii, and a number of small boats were lost at Waiakea. Four waves passed over Haleiwa, some thirty miles from Honolulu, which does not appear to have suffered important damage. The cable between Midway Island and Guam appears to be broken, and attempts to reach Samoa by wireless were unsuccessful. Mr. J. J. Shaw, of West Bromwich, Birmingham, states in the *Daily Mail* that the primary movement began on Saturday afternoon at 4 h. 13 m. 15 s., and the secondary at 4 h. 23 m. 4 s., indicating a distance of 5300 miles. The earth tremors continued for upwards of six hours. The needle was thrown off the record several times. Mr. Shaw states that the disturbance is the biggest recorded since the Chinese earthquake of December 1920.

THE annual meeting of the Iron and Steel Institute will be held on Thursday and Friday, May 10 and 11, at the Institution of Civil Engineers, Great George Street, London, S.W.1. The council has received a very cordial invitation from Mr. G. E. Falck, president of the Associazione Fra Gli Industriali Metallurgici Italiani, for the members of the Institute to meet in Italy in the autumn of this year. Subject to final arrangements with the Italian Association, the general meeting will be held at Milan about the middle of September, and on its conclusion it is proposed that visits should be paid to the principal metallurgical centres and to the hydro-electric power stations in Italy. The tour will also include visits to Rome, Naples, Genoa, and Turin, and is expected to occupy altogether about nineteen to twenty days from the time of leaving London until the return.

AT the recent annual meeting of the American Association, held at Boston, the Association as a whole declared itself unqualifiedly in favour of the metric system of measurement with one of the strongest resolutions ever passed by that body on this subject. The resolution is as follows: "Whereas the metric system of weights and measures has not yet been brought into general use in the United States, and whereas the American Association for the Advancement of Science has already passed resolutions favouring the adoption of the metric system of weights and measures in the United States; therefore be it resolved: That the American Association for the Advancement of Science reaffirms its belief in the desirability of the adoption of the metric system of weights and measures for the United States, and recommends that the units of the system be used by scientific men in all their publications, either exclusively or else with the customary non-metric units in parenthesis."

THE exhibition of facsimiles and reproductions of old maps in the Whitworth Hall of the University of Manchester during the last week of January coincided with the news that the Council of the University decided at the last meeting to recommend to the Court the institution of an honours school of geo-

graphy within the faculty of arts. The exhibition, arranged jointly by the Manchester Geographical Society and the University, was opened by Sir Frederick Lugard, and the occasion was taken to bring before the public the appeal for funds which the Society is making to endow a chair of geography in the new honours school. The collections of maps, which have been placed on loan at the University by Col. D. Mills and Mrs. Booker, include facsimiles of such maps as the Madaba Mosaic, the Peutinger Table, the St. Sever copy of the Beatus map, 14th and 15th c. portolani, the Catalan world map of 1375, and the series of maps reproduced principally under the direction of Prof. E. L. Stevenson, illustrative of geographical discovery in the period between the time of Juan de la Cosa's portolan (1500) and the world map of Hondius (1611). The Booker collection contains many typical country and county maps from Norden and Saxton to Cary, Greenwood, and Bryant, while the reproductions of London and Paris views and maps (Mills collection), made by the London Topographical Society and the French Government respectively, form excellent material for the study of these two cities. In addition, the exhibition includes a number of regional maps of the various parts of the world extending over a considerable period of time, of which those of Russia and the Far East are the most extensive. There is every prospect, with these maps as a nucleus, of a great development of all phases of cartographical studies within the University.

MESSRS. W. WATSON AND SONS, LTD., of 313 High Holborn, W.C.1, have issued a new edition of Parts 1 and 2 of their microscope catalogue. Included in the list is a new model, the "Kima," which is specially designed for students and sold at a reasonably low price. The instrument, which is somewhat similar to, but smaller than, the now well-known "Service" model, complies with the specification of the British Science Guild except in regard to the position of the fine adjustment milled heads. Various models—for example, the "Royal," the "Van Heurck"—suitable for research or general high power work, as well as binocular microscopes for both low and high powers are described in detail and a complete list of eyepieces, objectives, condensers, and other accessories is given. A welcome reduction in prices is noticeable in nearly all the items. There is also listed a horizontal or reading microscope consisting of a microscope body of large diameter fitted with a micrometer eyepiece and a 2-inch objective. The body is surmounted by a sensitive bubble for levelling purposes. Vertical adjustment is made by a rack and pinion, the pillar being divided into millimetres and fitted with a vernier.

THE Pasteur lecture delivered before the Institute of Medicine of Chicago on November 24 last, by Dr. Jacques Loeb, is reproduced in the issue of *Science* dated December 29. The lecture is devoted mainly to a consideration of the osmotic equilibrium of gelatin in the presence of various concentrations of acid and alkali.

WE have received the new issue of the chemical catalogue of British Drug Houses, Ltd. In many cases there has been a considerable reduction in prices of chemicals in everyday use, and some substances required by research workers are now listed which did not appear in former catalogues. Biological stains are included, and the catalogue should find a place in every laboratory.

IN the January issue of the Research Defence Society's pamphlet, *The Fight Against Disease* (Macmillan and Co., price 6*d*.), the story of bubonic plague, by Surg.-Gen. Bannerman, is retold (the Society first published it in 1910). An excellent account is given of the ravages of bubonic plague and its transmission from rats to man through the intermediary of the rat fleas. Some data are also included of the efficiency of plague vaccine in the prevention of the disease. The general article on Pasteur which appeared in NATURE, December 23, is also reprinted.

Our Astronomical Column.

FIREBALLS IN FEBRUARY.—Mr. W. F. Denning writes: "This month though it does not supply meteors in abundance has furnished a number of large fireballs, some of which have been of exceptional character. The Mon. Not. R.A.S. for March 1922 contained a list of the remarkable meteoric phenomena recorded in recent years between February 7 and 22. Two of the most singular fireballs ever seen occurred, one on February 22, 1909, which left a long streak in the sky for two hours and drifted on upper wind-currents to north-west at the rate of 120 miles per hour. The other, on February 9, 1913, consisted of a stream of bright meteors which passed over North America, and had a luminous flight extending over at least 5500 miles.

"It is impossible to foretell the time of appearance of any individual fireball, and it is necessary that observers should be specially on the alert during the present month, for the prospect of observing a large meteor is very good, especially during the periods February 7, 10–14 and February 19–22. There are several active radiants at this time of the year, such as those at 147° − 11°, 167° +33°, 73° +42°, and 106° + 52°. In the event of any bright meteors being seen, the particulars should be carefully noted, and their apparent paths among the stars recorded as accurately as possible."

ASTRONOMICAL CIRCULARS.—There is a class of astronomical announcements—discoveries of comets or of novae, unusual markings on planets, etc.—the early circulation of which is of importance to observers. In the last century Lord Crawford started the Dunecht and Edinburgh Circulars, but they were not continued after his death. The only resource up to the present for those who find the price of astronomical telegrams too high has been the series of circulars issued by Prof. Strömgren at Copenhagen, or that of the *Astr. Nach.* at Kiel. These take some days to reach this country. The British Astronomical Association has now decided to issue a series of circulars when news of an urgent character comes to hand. Non-members of the B. A. A. can obtain these circulars at a charge of a few shillings per annum on writing to the secretary. They will include the latest ephemerides of comets in addition to discovery announcements.

Research Items.

THE FAROE ISLANDS.—The Faroe or Sheep Islands, lying half-way between Iceland and the Shetlands, are inhabited by people of Norwegian descent. In these islands an energetic linguistic movement has recently arisen, aiming at elevating the local idiom to the rank of a language, a movement which is not political, but suggested by the declaration in 1918 of the independence of Iceland. Mr. J. Dyneley Price, in the Proceedings of the American Philosophical Society (vol. lxi. No. 2, 1922), describes the linguistics and phonetics on information furnished by Miss M. E. Mikkelsen, a Faroese lady now resident in Copenhagen. It is curious that this movement extends to a new form of spelling which, like the stereotyped archaic spelling of modern Gaelic, ignores the modern phonetics of the spoken dialects.

AN ANCIENT AUSTRALIAN SKULL.—Anthropologists will read with considerable interest a paper in the *Journal of Anatomy* (vol. lvii. part 2) by A. N. St. G. H. Burkitt and Prof. J. I. Hunter on "A Description of a Neanderthaloid Australian Skull." This was that of a female, and was "Neanderthaloid" only in so far as the calvarium was concerned. The excessive development of the supraorbital ridges of this skull the authors ascribe largely to the action of the masticatory muscles; but their arguments in favour of this interpretation, which are shared by others, are not convincing. In the conclusions at which the authors have arrived, we hoped to find some expression of opinion as to the precise relationship of this skull—and of the Australian aborigines in general—to Neanderthal man. But on this matter no direct views have been advanced. The authors applied several tests to discover the alveolar index of this skull. "Flower's Gnathic Index," they remark, "places it well within the limit of orthognathic skulls, the index being 95·23." The base line devised by Pycraft gives an index of 96, when applied to the photograph of the skull on Plate I. We venture to think that the authors have laid undue stress on the "Neanderthaloid" characters of this skull, and we are puzzled by the cryptic statement that "we must regard the cranial resemblances as an expression of the principle that descendants of a common ancestor show a tendency to develop independently similar features."

NITROGEN FERTILISERS FOR THE SUGAR CANE.—In the *Archief voor de Suikerindustrie in Nederlandsch Indië* (1922, Mededeelingen No. 3) J. Kuyper describes experiments carried out in Java on the relative value of several nitrogen fertilisers for sugar-cane cultivation. The trials have been carried out for several years in comparison with sulphate of ammonia, of which the average amount used is about 380 lb. per acre. In all cases the same weight of nitrogen was given in the different manures. Urea and nitrate of soda proved to be equal in value to ammonium sulphate, but the nitrate is too hygroscopic for convenient use. The same objection applies to ammonium sulpho-nitrate, especially in the tropical rainy season. Nitrolim or cyanamide and beancake are both of less value. Beancake does better on some soils than others, and is improved by the admixture of a certain proportion of sulphate of ammonia.

PASTURE GRASS IN TROPICAL AFRICA.—It is difficult to overestimate the importance of the contributions to colonial development that may be made by the work of institutions such as the Royal Botanic Gardens, Kew. The *Kew Bulletin* (No. 10, 1922) contains a typical example of the type of information which the resources of such a central institution can so readily place before various interested outliers of Empire. In western tropical Africa one of the difficulties in the way of pasturing fertile country lies in the ravages of the tsetse fly and the epidemics it engenders. Mr. T. M. Dawe, making an agricultural survey of Angola in 1921, recognised in the native "Efwatakala grass" a fodder plant similar to a Brazilian grass already known to him as capable of fattening stock. This grass was widely distributed in the Portuguese Congo, and on its receipt at Kew it proved to be *Melinis minutiflora*, Beauv., *f. inermis*, already reported upon in the *Kew Bulletin* (1900) as "Brazilian stink-grass." Dr. Stapf's report in the present bulletin fully bears out Mr. Dawe's view that the grass should prove a rapid coloniser of open ground and then form a fairly permanent pasture. Its potential value lies, however, in the insecticidal or insect-repelling qualities of an oil secreted in glandular hairs upon the leaf-sheath and lamina. The grass has now been grown upon a small scale at Kew, and the Jodrell Laboratory supplies a note upon the structure of the glandular hairs while the Wellcome Research laboratories have made a preliminary study of the small quantity of oil that could be extracted from the available crop of the grass. Mr. Dawe apparently hopes that this grass may prevent the spread of the tsetse fly at the same time that it provides food for stock. If such anticipations are realised the ultimate possibilities of its cultivation in tropical Africa are incalculable. It would be interesting to learn why the attempt at its introduction into Australia, chronicled in the earlier note in the *Kew Bulletin*, seems to have been without result.

THE PALOLO WORM.—Dr. Glanvill Corney, who was for many years chief medical officer of Fiji, contributes an interesting paper to the Journal of the Torquay Natural History Society on the periodicity of the sexual phase of the "Palolo" worm in Fijian waters. This worm (*Eunice viridis*) lives in the coral skeletons and rocks of the reefs, riddling them with its burrows. Like most bottom-living marine animals, its eggs are cast on the mercy of the waves and currents to be distributed far and wide. While most boring worms are content merely to shed their eggs into the bottom waters, several kinds, including the Palolo, cut off the hinder parts of their bodies, which are crowded with generative cells; these float to the surface of the water, each segment rupturing and setting free its sexual cells: this is known as swarming. The first phase of development is a floating one, but the larvæ soon settle and form their burrows. Annually the worm sheds its hinder sexual part into the water and re-forms it. The peculiarly interesting feature of the life history is the regularity with which this phenomenon occurs. As usual in such forms, the generative organs are ripe in the spring of the year, when there is a peculiar outburst of all life. The Palolo swarm on the same day, the surface of the sea at dawn becoming thick with their bodies. The day selected at Fiji is recorded by Dr. Corney for 25 years and is shown always to be on the morning of the seventh to ninth days after full moon in November or early December: the interval between swarming is sometimes 353-6 days and at other times 382-6 days, either 12 or 13 lunar months. A few may swarm a month earlier at the corresponding neap tide, but this small swarm is often unrecognisable. The vast

quantities of sexual Palolo in the surface waters, like a thick macaroni soup, is a striking phenomenon enough, but it is one greatly enhanced by other eunicids, other worms, many crustaceans, and other animals all breeding in the same days of lowest tides, when the reefs are subjected to the greatest amounts of heat and light; indeed, similar sexual correlations with solar and lunar phenomena have now been suggested in nearly every group of animals.

THE ETESIENS IN THE MEDITERRANEAN.—An article is given in the U.S. *Monthly Weather Review* for August 1922, by Mr. J. S. Paraskévopoulos, of the National Observatory, Athens, on the etesiens, the characteristic north winds which blow during the summer in the region of the eastern Mediterranean. The marked regularity of these winds was observed by the ancient Greeks and the name signifies "winds blowing periodically every year." The author has tabulated the data for several Greek meteorological stations, and for a period extending over 15 years, 1900–14; the observations are made three times daily, at 8 A.M., 2 P.M., and 9 P.M., while for Athens the observations are continuous from self-recording instruments. The etesiens blow generally from the second 10-day period of May until the middle of October, with two periods of maximum. During June the winds are interrupted; in July and especially in August they are much more steady and frequent. In Athens before the middle of July the etesiens blow during the morning and are replaced in the afternoon by the sea breeze. The principal features of these winds have been known since the time of Aristotle. The anemometric data at Athens show that the velocity of the etesiens undergoes a very distinct diurnal oscillation; the speed during the daytime varies from 11 to 27 miles per hour, and it seldom reaches 45 miles per hour. Information is given as to their origin, with respect to the distribution of atmospheric pressure, temperature, and humidity. As they contribute largely to the dryness of the soil, they raise by their motion great quantities of dust.

THE HUMBOLDT CURRENT.—Variations in the temperature of the Humboldt current have been noted for many years and were recently examined by Mr. R. C. Murphy, who contributes an article to the *Geographical Review* for January on the oceanography of the Peruvian littoral. The uniform temperature conditions of this current are carried southwards from Peru at least so far as Valparaiso. Throughout this extent the lowest surface temperatures are in the inshore waters and are due to the upwelling of bottom water which is the feature of this current. The steeper the coastal slope, the greater is the reduction of inshore temperatures. Irregular variations in temperatures, which occur locally throughout the year, have been generally attributed to a shifting in the course of the current. Mr. Murphy believes that the cause is to be found in the northerly winds which accompany these abnormal sea temperatures. These winds drive warmer waters inshore and temporarily check the upwelling. More prominent is the current known on the Peruvian coast as El Niño. This counter-current of tropical water is felt seasonally north of about lat. 8° 13′ S. Mr. Murphy demolishes the theory that El Niño is due to the waters of the River Guayas and holds that it can be correlated with changes in barometric pressure when the sun is south of the equator. The paper ends with some interesting correlations between the temperature variations of the Humboldt current, the distribution of plankton, and the valuable guano birds of the Pisco Bay region. The invasion of warm water destroys enormous quantities of plankton. The result is that the birds either migrate or have to face a loss of food supply. The latter course leads to a lowering of vitality and considerable reduction in numbers as the outcome of certain prevalent diseases which attack the weakened birds.

EARTHQUAKES OF THE EAST INDIAN ARCHIPELAGO.—In a recent important memoir (Konin. Magnet. en Meteorol. Observ. te Batavia, Verhandelingen No. 7, 1921) Dr. S. W. Visser has investigated the distribution of earthquakes in the East Indian Archipelago from 1909 to 1919. The positions of the epicentres were determined from seismograms at the observatories of Batavia, Malabar, Manila, Sydney (Riverview), and Zikawei. Earthquakes strong enough to be registered at two or more of these observatories (160 near Western Java and 120 in other parts of the Archipelago) are confined as a rule to four principal regions—the Indian Ocean off southern Sumatra and western Java, the Celebes Sea and the Pacific Ocean south of Mindanao, the southern and eastern borders of the Banda Sea, and the mountain ranges of New Guinea. With the exception of the last region, the seismic zones of the Archipelago coincide with the steeply sloping sides of oceanic troughs in the close neighbourhood of the islands. The bottoms of the Indian and Pacific oceans far from land are probably nearly or quite aseismic. In a second memoir (Verhandelingen No. 9, 1922) Dr. Visser studies the earthquakes with an inland origin in Sumatra and Java only, the materials for the other islands being insufficient. They are few in number. For example, during the thirteen years 1909–1921, 13 earthquakes out of 859 in Sumatra, and 6 out of 748 in Java, had an inland origin. The distribution of inland earthquakes in Sumatra is simple and regular. Most of the epicentral areas coincide with a long fracture which has given rise to an important series of longitudinal valleys in the Barisan mountain ranges. In Java the distribution is less regular. Violent earthquakes have occurred on the slopes of some volcanoes (for example, Mount Gede and Mount Tjerimai). They were, however, of tectonic origin, the proximity of volcanoes being only a coincidence or due to their connexion with the same zones of weakness. At the times of severe earthquakes the activity of the volcanoes was either slight or altogether absent.

TROUTON'S LAW.—When in 1884, in volume 18 of the *Phil. Mag.*, Trouton showed that for a number of liquids the molecular heat of evaporation at the normal boiling-point was 20 times the absolute temperature at that point, the data by means of which the law could be tested were scarce and the accuracy of the values available not great. Additional and more trustworthy data were provided by Louguinine in 1896–1902 and the law shown to hold to within 10 per cent. for groups of liquids of similar constitution, but to be sometimes 50 per cent. in error when, for example, alcohols were compared with organic acids. Further work has disclosed many exceptions and attempts have been made to find temperatures other than the normal boiling-points at which the comparison would give more consistent results. These have, however, been unsuccessful, and in the January issue of the *Phil. Mag.*, Mr. S. B. Mali, of the University of Calcutta, states that there is no temperature at which the law holds, that it has no theoretical significance, and that it is an accident that it appears to hold for some substances at their normal boiling-points. This may be the correct view, but it is still remarkable that many liquids should fall into the accidental group.

Can Gravitation really be absorbed into the Frame of Space and Time?

By Sir JOSEPH LARMOR, F.R.S.[1]

AN answer to this question in the negative has been advanced in a previous paper on the gravitational deflection of light (*Phil. Mag.*, Jan.). The destructive paradoxes concerned with the recent gravitation theory, which were unfolded by M. Jean Le Roux, professor at Rennes, in three notes in the *Comptes rendus* (Nov. 6, Dec. 4 and 22), after that paper was completed, were referred to in a footnote in support of this departure from the familiar answer. These objections require to be further considered; for at first sight they are destructive to all such theories, including the modification there substituted. If an orbit is postulated to be a curve of minimal length in a fourfold expanse of space-time, the element of length (or distance-interval) must be expressed for it locally, and can involve as variables only its own co-ordinates and their differentials. Yet in the cases that have been worked out, the element as determined involves also the concurrent co-ordinates of the other interacting masses; with all these variables present, it could not belong to a curve in a fourfold at all. This destructive dilemma applies very widely.

There may be a suggestion to evade it, in the theory as modified into one of dynamical Action, along the line (already indicated by A. A. Robb) that the idea of distance cannot subsist in the pseudo-space at all. For within an infinitesimal fourfold spherical domain with radius a very small interval *ds*, the co-ordinates would have an infinite range of values. The idea of locality, essential to real space, is thus absent. The fourfold expanse could still be utilised to express conveniently the domains of integration: but where distances have to enter they must be in threefold real space, though it can be variable and be associated with time also variable. Such real spaces and times would be locally not unique; they constitute a Lorentz group of interchangeable forms. The modified gravitational scheme of the previous paper, with its reduction of the influences on radiation to one-half of the accepted values, might, merely by avoiding the idea of fourfold interval interpreted as a geometric distance, possibly still manage to evolve as a dynamical formulation.

But this train of ideas need not be pursued; for in fact the criticism, which seems destructive of a quasi-geometric scheme for gravitation, does not inhere at all in the dynamical domain of Action. The type of procedure for minimising the total Action, when more closely exhibited, would run in principle as follows. Assume some approximate specification for the orbital paths in the fourfold, close of course to the Newtonian solution. The orbits thus assumed will determine the nature of the fourfold space-time expanse (namely ds^2) already adjusted to minimal Action, in which they exist. For each such specification calculate the density of Action in this fourfold expanse, after the manner of approximate modifications as developed by Einstein; and thence find by integration the total Action of the system corresponding to these assumed orbital forms. The forms of the orbits would enter in the expression for the linear element *ds* defining the space determined by these orbits and necessarily containing them. By taking varied forms of the orbits, different forms of *ds* and different values of the total Action would be obtained. The aim would be to adapt the forms of the orbits so that the Action thus determined from them should remain stationary for all slight variations. The way to carry this out would be to minimise the Action further for joint variation of all the orbits, exactly on the lines of the previous paper. The space itself, being determined by the orbits, also changes as the orbits are varied; and it is not at all involved that *ds* remains the elemental distance in the *same space* throughout the procedure.

It would appear then that the Minkowskian method of fourfold spatial analysis as generalised by Einstein for adaptation of gravitation into the optical and electrodynamic group of frames, can be saved from the destructive criticism of M. Le Roux. But to this end the postulate of absorption of gravitation into the spatial frame must be abandoned; and the principle of equivalence of gravitation and acceleration would disappear. The application of the mathematical spatial analysis to astronomy and optics would be reconstructed as a dynamical theory of normal type, unfolding itself in terms of a distribution of Action located ultimately throughout the region of the problem: but the results as modified would still require actual confirmation. If, however, any gravitational influence on light is finally established by the astronomical observations, this type of analysis by aid of a varying spatial frame may remain the most effective way to include it in theory.

[1] Abstract of a paper read on January 22 at the Cambridge Philosophical Society.

The Nature of Gels.

By Dr. S. C. BRADFORD.

IT has been known, probably from the earliest times, that when sufficiently concentrated solutions of certain substances, such as gelatin and agar-agar, are allowed to cool, instead of depositing crystals of the dissolved substance, the whole liquid turns into a jelly. It is natural, therefore, that speculations on the nature of jellies should have been rife long before Graham, in 1861, first pointed out the slow rate of diffusion of colloid substances which distinguished them from bodies which separate from solution in the ordinary crystalline form.

The many theories of gel structure fall naturally under three heads: (1) One-phase or molecular systems, (2) two-phase liquid-liquid systems, and (3) two-phase liquid-solid systems. To the first class belongs Proctor's hypothesis that a gel is a more or less solid solution of a liquid in the colloid substance, in which both constituents are within the range of molecular attractions. This view is very similar to the "super-cooled liquid" theory of glass, and, like that, has difficulty in explaining the loss of mobility which occurs on setting. Proctor suggests that the transformation consists in the formation of tenuous crystals, which interlace and possibly anastomose. Later experiments[1] show that gelation is really an extreme case of crystallisation, but this suggestion would bring Proctor's theory into the third class. In either case, however, his experiments are important, as they show that the swelling of gelatin in

[1] Bradford, *Science Progress*, 1917, 12, 62; *Biochem. Jour.* 1918, 12, 357; 1920, 14, 91; 1921, 15, 553; and "The Physics and Chemistry of Colloids," Discussion by the Faraday Society, etc., London, 1921.

acids can be explained by simple chemical and physical laws.

To the second class belong both Hardy's and Wo. Ostwald's theories that gels are composed of two liquid phases. Theories of this type present the same difficulty as those of the first class in explaining the increase of viscosity during gelation. No emulsions are known having properties really like those of gels. Nor can liquid-liquid systems be imagined with the elastic properties of gels. Moreover, no hypothesis in either of these classes is sufficient to allow the deduction of the various properties of gels, and there is little direct evidence for any of these suppositions.

The third type of theory, that gels contain both liquid and solid, is the most natural, and was the earliest to be proposed. The first definite suggestion appears to have been made by M. L. Frankenheim in 1835, who thought that jellies were aggregates of small crystals with pores between them. A similar view was adopted in 1879 by K. von Nägeli, that such bodies were composed of molecular complexes, or micellæ, with crystalline properties, separated by skins of water and forming meshes (or interstices) in which the water was contained by molecular attraction. From the use of the German word *Maschen* it has been inferred that von Nägeli intended a geometrical framework. But it is not necessary to assume that he meant more than that the water was held by molecular attraction in the interstices of the aggregates (within and between), and that the aggregates were separated by capillary skins of water. This view is almost exactly that which must be accepted as the result of recent experiments. However, since von Nägeli, a number of unsuccessful attempts have been made to devise a mathematical network which would account for the elastic and thermal properties of jellies; it has scarcely been recognised that such a framework must conform to the facts that the elastic properties of different gels differ greatly, and that the different directive forces inherent in the ultimate particles of different jellies must have some effect on their structure. On this account it seems unlikely that a single framework would be found to satisfy the different properties of different gels; it appears more probable that the structure of gels will be found to vary according to the nature of the gel substance.

O. Bütschli's extensive researches on foams and gel structure are well known. He came to the opinion that the properties of gels might be explained on the basis of a honeycomb structure, in which the walls were permeable to liquids because of their extreme thinness, although they might be porous. To this it must be objected that the use of alcohol and tanning reagents to bring out the microstructure, adopted by Bütschli, and later by Moeller, is open to objection, as being likely to alter the structure of the gels or to modify the gelation process. Moreover, Zsigmondy and Bachmann have demonstrated, from the vapour pressure isotherms, that gels must contain fine pores with a radius of from 2·5 to 5 $\mu\mu$, some 300 times smaller than Bütschli's honeycombs. From microscopic work on soap curds and gels, these workers and McBain have favoured a fibrillar structure. This view has also been adopted by Moeller for gelatin, and is supported by Barratt from experiments on fibrinogen gels. For the soaps and fibrinogen there is direct microscopic evidence that fibrils can be formed by the cooling solutions, indicating that the ultramicroscopic structure of their gels may be fibrillar. In other cases a globulitic structure is indicated. Menz observed the development of submicrons in gelating 2 per cent. gelatin, which increased from 4, showing Brownian movement, in a square division of the field with a side of 9 μ, to 80 or 100, at rest, in the same area. Hardy describes the appearance of microscopic spherites of 10 μ in gels of 5-dimethylaminoanilo 3 : 4-diphenyl*cyclo*-pentene-1 : 2-dione, and Bachmann showed that the ultramicroscopic appearance of gelatin gels deprived of water is globulitic.

Thus there is much evidence for the liquid-solid type of theory. Nor is Debye and Scherrer's X-ray analysis sufficient to show that the ultimate particles of gels are not crystalline, because the radial elements of the spherites, in which form experiments show gelatin and agar-agar to be deposited from solution, cannot be composed of many layers of molecules, and it is doubtful whether such complex molecules could produce appreciable interference of monochromatic X-rays.

But none of the theories mentioned is sufficiently definite to permit the deduction of the properties of gels and the explanation of the reversible sol-gel transformation. Nor do they suggest a reason why such substances as gelatin and agar-agar should occur invariably in the colloid state. The latter question proves to be a crucial one. Investigation shows that, in this respect, there is no fundamental difference between gelatin and other substances—that the same laws govern their solution and precipitation; and gelation is merely a limiting case of crystallisation.

In this connexion the researches of von Weimarn are of fundamental importance. From a great many experiments with such substances as barium sulphate and aluminium hydroxide he deduced an empirical formula,

$$N = K\frac{P}{L},$$

which expresses a relation between N, the "form coefficient" of the precipitate, and K, P, and L, respectively functions of the viscosity of the reaction medium together with the size and structure of the particles in solution, the excess concentration of the substance to be precipitated, and its solubility. Von Weimarn was able to show that as N increases, the precipitate passes through stages in which it appears as (1) large complete crystals only after some years, (2) ordinary crystals in a short time, (3) growth figures or needles, (4) amorphous precipitates frequently showing microscopic spherical grains, and (5) as a gel which cannot be differentiated by the microscope. The formula suggests at once that gelation is merely an extreme case of crystallisation, and that gelatin is a substance the properties of which lead naturally to a high value of N. This is completely borne out by experiment. Not only do the properties of gelatin sols coincide with those of supersaturated solutions, but by reducing the value of N, gelatin is readily obtained as a precipitate, with particles microscopically visible. The solubility of ashless gelatin in water is found to be 0·12 grm. per 100 grm. solution at room temperature, *i.e.* about 18° C. More recently Fairbrother and Swan found the value 0·07 per cent. at 18° for another brand containing 2·24 per cent. of ash. Such a solution is perfectly clear. At 0·13 per cent. gelatin forms a metastable solution, which remains in the supersaturated stage on account of the very low diffusion constant of the substance. This solution has a beautiful bluish opalescence and may be regarded as a typical sol. A further slight increase in concentration brings about the precipitation of the excess of gelatin as a gelatinous mass appearing in the microscope like grains of sand. Many of the particles can be separately distinguished; they are spherical in form and up to about 2 μ in size. With increase of concentration, the bulk of the precipitate grows and the particles decrease in size until, at about 0·7 per cent., the precipitate fills the solution and forms a white, slightly opaque jelly. The

opalescence gradually disappears as the gel particles become smaller with increasing concentration. Gelatin jelly is therefore a gelatinous precipitate of gelatin of at least 0·7 per cent. concentration.

The size of the particles can be increased by allowing them to grow by spontaneous evaporation of the solution, subject to the necessary precautions. After one month the precipitate is buff-coloured, and appears as a mass of perfectly spherical microscopic grains exactly like Perrin's grains of mastic. From these and many similar experiments, in conjunction with the ultramicroscopic appearance, it may be concluded that a gelatin jelly is a mass of ultramicroscopic spherites of gelatin in which, as von Nägeli suggested, the water is held by molecular forces. These forces are the cause of the swelling in water, and the heat of swelling can be calculated roughly on this supposition. The structure fits exactly Zsigmondy's analysis of the vapour pressure isotherms. Experiments on the relation between the excess concentration and the size of particle are being made and may lead to a more definite form of von Weimarn's equation. But, in its present state, the formula is sufficient to explain the occurrence of gelatin in the colloidal state. The molecular weight is unknown, but Dakin's recent analyses suggest that it may be as great as 10,000, or more, a value which would correspond to a molecular diameter of 0·75 $\mu\mu$ and bring its molecules up to colloidal size. But, though the molecular weight should be much less, there is no doubt that the molecules are very complex, for this is the reason for the very low diffusion constant; moreover, as the viscosity also of the sols is considerable, the factor K must be very large. In addition to this, the solubility, L, is very small, and the excess concentration, P, is usually large, so that everything conspires to produce a maximum value of N corresponding to the colloid condition. The permanence of the jelly is due to the very small diffusion constant, which prevents recrystallisation. But this does occur slowly, as is shown by the gradual appearance of opalescence, and even of microscopic spherites, in gels kept for a long time in sealed tubes.

Since agar-agar also separates from solution in the form of spherites, it appears that the structure of gels of this substance and of gelatin is probably that of a pile of shot, while soap and fibrinogen gels may be fibrillar. Such a fine-grained structure is compatible with all the known properties of gels, except the heat of swelling of gelatin, 5·7 cal. per grm., and the so-called thermal anomaly. Re-determination of the former gave 33·25 cal., and investigation of the latter showed that it was unfounded. Two questions remain undecided: (*a*) The nature of the spherites and (*b*) whether they are joined together to produce a framework in the jelly. Spherites are known in every gradation, from the obviously crystalline form, built up of coarse radiating crystalline needles separately visible, through stages showing only a more or less radiating formation, but giving the well-known shadow-cross in polarised light, to apparently homogeneous spherical bodies giving no definite evidence of crystalline structure. Gelatin and agar-agar spherites appear to belong to the last class. Experimental evidence suggests that the spherites coalesce during gelation. They would seem either to aggregate crystallographically or to adhere by their mutual attraction; or, the apparent attraction may be due to the water molecules having a greater mutual attraction than the spherites. It will be admitted, however, that, in the case of such small particles, there can be very little difference between the two former methods of attachment, since the union must be due to the forces between the few molecules in the surface of contact. With two grains only, the coupling would be unstable, but it would become firm as more grains were added.

Since writing the above, evidence has been obtained that the gelatin spherites are really crystalline. Some of these, grown to a size of about 3 μ, by methods previously described, and mounted in glycerin, were examined with polarised light. When the Nicols were crossed they became brilliantly coloured and many showed shadow crosses, while grains of mastic prepared by Perrin's method and mounted in the same way became invisible. These experiments are being continued, but, without evidence to the contrary, it will be difficult to deny that gelation is merely an extreme case of crystallisation.

Physical Properties of Clay and Clay-Mud.

MUD and clay are materials, the properties of which are not only of concern to the meticulous housewife and to the children who make mud pies and clay engines; the geologist has found interest in their formation, and from the study of them is able to trace a large part of the history of the earth's crust. They have played their part in the æsthetic development of the race. They have been the architect's and engineer's friend for the making of building materials, and have filled them with concern and not infrequently dismay when they have desired to build upon them or when they desired to support them. The story of the development of buildings, bridges, and other types of structures, tells of many failures, because of the treacherousness and uncertainty of these materials, and partly, at least, because engineers and architects had not attempted to determine their properties in a scientific manner.

Mr. A. S. E. Ackermann has presented, during recent years, four papers to the Society of Engineers in which he has described experiments to determine the physical properties of clay and the effect of water content upon their properties.[1] He has shown that, like certain metals, clays have a certain measure of fluidity. When a disc resting on clay is loaded the disc sinks into the clay, the amount it descends depending on the load and on the time allowed; and when the load exceeds a certain amount, which depends upon the amount of water present, the rate and extent of penetration are considerably increased. The stress at which this occurs, Mr. Ackermann has called the pressure of fluidity. Mr. Ackermann's experiments have been directed toward determining the bearing power of soils, and the loads that can safely be applied to them.

The difficulty of reconciling experimental data on the properties of these materials is evidenced by comparing the results of experimenters. Mr. Ackermann states that the friction angle for wet mud varies as the square root of the pressure, while Crosthwaite says it is proportional to the square root of the pressure. A special committee of the American Society of Civil Engineers to codify present practice on the bearing values of soils for foundations, has issued a series of reports, and has emphasised the importance of the colloid content of clay, which consists of non-crystalline, hydrated, gelatinous aluminium silicates, gelatinous silicic and hydrated ferric oxides; rarely aluminium hydrate may also be present. Most of the grains of the minerals in the clay are enveloped by colloid, but quartz grains

[1] Society of Engineers Transactions, 1919-20-21-22.

do not, as a rule, have the colloid coating. The plasticity of the clay depends upon the amount of colloid present. To separate the colloidal from the granular material, the clay is revolved at 40,000 revolutions per minute in a separator.

Dr. Hubert Chatley, in a recent paper,[2] has discussed the properties of clay-mud, and states that it has three special features:

(1) A granulated structure of varying degrees of fineness.

(2) A semi-permanent water content, which gives it peculiar mechanical properties.

(3) A certain small reserve of chemical potential, which, under certain conditions, will cause it to change in various ways.

He discusses the methods of observing the granular matter by means of the microscope, and states that the plasticity depends upon the size of the products and the proportion of colloids present. He divides the water content into three classes.

Clay-mud containing 15 per cent. by weight of water has a tensile strength of 15 lb. per sq. inch, but doubling the water content reduces the tensile strength to one-third of this amount. With 28 per cent. of water, its viscosity is about the same as a heavy grease, corresponding to a shear strain of 1 radian per 100 seconds, under a shear stress of more than 100 grm. per sq. cm. It differs from heavy grease, however, in that water is extruded as the pressure is increased. It is not watertight, and dykes allow water to percolate very slowly, but if the surface of the dyke is dry, the surface tension may arrest the flow.

The results of the data indicate agreement with common experience that the water content of clay is of great importance, and they also indicate that, as with all other materials, the working stresses should be within the "elastic range."

Silvanus Thompson Memorial Lecture.

AT the request of the Finsbury Technical College Old Students' Association, Sir Oliver Lodge gave the first of these lectures at the College on February 1, Sir Charles Parsons in the chair, to an audience numbering more than a thousand and including many eminent past students. After a reference to the splendid work of the College in the past, and its hopes for the future, the lecturer recalled the brilliant succession of teachers—Ayrton, Perry, Meldola—colleagues of Thompson. Of the latter he said: "The breadth of his outlook and width of his interests are almost proverbial; his facility in foreign languages enabled him to hold his own in assemblies abroad, and he had a real artistic faculty. He had a love of discoveries in their nascent stages, and became a recognised historian of science. To a man of his cosmopolitan feelings and pacific disposition, the war and its atrocities were a great distress; grief and worry and overwork overtook him, and he succumbed on June 12, 1916—a victim of the war—having been principal of Finsbury since 1885."

Proceeding to the subject of the lecture, "The Origins or Foundations of Wireless Communication," and confining himself to matters prior to 1896, Sir Oliver recalled that the term "inductance" did not at first exist; Lord Kelvin introduced it as a mathematical coefficient, Maxwell spoke of self-induction, and Heaviside originated the term now used. In the early work on the production and detection of electric waves in the ether, Kelvin, Maxwell, FitzGerald, and Hertz laid the foundations which made the present superstructure possible.

In 1875 Edison observed the possibility of drawing sparks from insulated objects in the neighbourhood of an electrical discharge; already in 1842, Henry, in Washington, had surmised—through a similar observation—that there was some similarity between the etherial disturbance caused by the discharge of a conductor and the light emitted from an ordinary high-temperature source. Early in the 'eighties David Hughes, working with the microphone and galvanometer, got something like a coherer, but was discouraged from pursuing the matter. In 1865 Maxwell gave the theory of electric waves, before their generation or detection was understood; he showed that they would travel with the velocity of light, that light was an electromagnetic phenomenon, that conductors of electricity must be opaque to light, and that the refractive index of a substance was intimately related to its dielectric coefficient.

This discovery aroused great enthusiasm, and one result was to influence the lecturer to devote his life to the study of electric waves; he discussed them with Fleming and FitzGerald, and spoke about them at the British Association in 1879 and later. In 1883 FitzGerald proposed the generation of the waves by using the oscillatory discharge of a Leyden jar, and the lecturer, in 1887, produced and detected them. The waves were received on wires adjusted to the right length for resonance. The experiments of Hertz, who received the waves on a nearly closed ring of wire having a short spark gap, were reported by FitzGerald at the British Association meeting of 1888, and Sir Oliver calculated the horse-power of the oscillator—about 100, for a millionth of a second; he exhibited many of the effects of the waves at the Royal Institution in 1889, but there was nothing akin to signalling; that was foreshadowed, in 1892, together with the possibility of tuning, by Sir William Crookes, who spoke of wave-lengths with which to signal to specific people, and alluded to Hughes's signals made from room to room without intervening wire.

In 1890 Sir Oliver employed a form of coherer to complete a bell circuit, and in 1893 heard of Branly's filings-coherer. In memory of Hertz, for whom Sir Oliver expressed the greatest admiration, both on account of his experimental skill and mathematical thoroughness, he gave a lecture at the Royal Institution on the work of Hertz; at this lecture actual signalling with a coherer was demonstrated. This work led to the grant of Lodge's patent in the United States, which was the fundamental patent of the American Marconi Company. The lecture stimulated Dr. Muirhead, Captain (now Admiral Sir Henry) Jackson, Admiral Popoff, Prof. Righi, and others to their experimental successes; in 1896 Mr. Marconi came to this country—and the rest is common knowledge.

After the lecture the audience was entertained at a conversazione in the laboratories. A beautiful collection of Dr. Thompson's paintings was on view, together with a number of his works, including a translation of Gilbert's "De Magnete" (1601) and a copy of the original. Coils constructed by Faraday, the first Nicol prism, a coherer made by Sir Oliver Lodge, acoustical and optical models, and many personal relics were lent by the late Doctor's family. Mr. W. M. Mordey, president of the Old Students' Association of the College, gave a demon-

stration of some effects of alternating magnetism on iron, nickel, cobalt, and ores of these metals, and on Heusler alloy. Prof. E. G. Coker showed the action of cutting tools working on a transparent medium by means of polarised light, using for this purpose Dr. Thompson's large Nicol prism, and Prof. C. H. Desch exhibited a number of lantern slides illustrating the structure of steel and non-ferrous alloys. Dr. Eccles, principal of the College, and a number of past students had interesting exhibits.

Pasteur.

ON Friday last, February 2, an address on the work and ideals of Pasteur was given in the rooms of the Royal Society by Dr. Pasteur Vallery-Radot, the grandson of Louis Pasteur. This was the first of a series of lectures, organised by the Alliance Française to be given by Dr. Pasteur Vallery-Radot in this country, in commemoration of the centenary of Pasteur, which is being celebrated this year. Sir Charles Sherrington, president of the Royal Society, was in the chair, and among those present at the meeting were Sir Anthony Bowlby, Sir Humphry Rolleston, Sir William Hale-White, Sir Charles Ballance, Prof. C. J. Martin, and Mr. Chaston Chapman.

Dr. Pasteur Vallery-Radot prefaced his remarks by saying how much he appreciated the homage which this country was paying to his illustrious grandfather, since it was in England, the home of Jenner and Lister, that Pasteur found some of his most ardent supporters. He contrasted the state of medicine before the advent of Pasteur with what it was at the end of the nineteenth century, showing what immense benefits had accrued to humanity at large from the brilliant researches of this great man.

In the short period of forty years, Pasteur lifted the study of infectious disease out of the morass of empiricism and placed it on a scientific basis. By his discoveries he opened up a new world, the realm of micro-organisms, and laid the foundations of bacteriology, which to-day occupies so important a position in medicine and many industries. The numerous investigations of Pasteur, commencing with his work on the tartrates and paratartrates at the age of twenty-six, were next rapidly passed in review. His fundamental discoveries in fermentation, his investigations on the disease of silkworms, chicken cholera, swine erysipelas, anthrax, these were all dealt with in logical sequence leading up to the masterpiece of this scientific genius, anti-rabies inoculation.

Perhaps to many this story was not new. It bears repetition, however, not only because of its enthralling interest, but because of the lesson which can be learnt from it. There are many, even to-day, who are only too ready to point the finger of scorn at scientific investigation or to oppose animal experiments. If only these misguided individuals were to make a study of the life and work of Pasteur, perhaps many of the grotesque criticisms of research would remain unuttered. To what did Pasteur owe his great success? We are told that as a youth at the Lycée he showed no promise of great achievement in life, that he was no more than an average pupil. He was, however, endowed with an imagination which served him well in planning his investigations. Coupled with this gift was a critical faculty which he applied rigorously to all he did—an unusual combination. It was, however, his faith in the experimental method, his fundamental honesty, his single-mindedness and his immense desire to advance knowledge and work for the good of humanity, which enabled Pasteur to achieve what he did. Inspired by this ideal, he went from one success to another, carrying all before him. Despite this, Pasteur remained simple and unostentatious to the end; he was indeed a great man.

Pasteur and Lister are perhaps the two most beautiful characters among the scientific men of the last century. Their lives should be read and studied by all those entering upon a career of scientific investigation. With such a model as Pasteur and fired by some of the idealism and enthusiasm of this great man, even those of mediocre attainments would achieve success. S. P. B.

University and Educational Intelligence.

CAMBRIDGE.—Another important development of the Agricultural School of the University is foreshadowed in an offer from the Ministry of Agriculture and Fisheries announced by the Council of the Senate. In the first instance the offer is of a sum of 30,000*l.* from the Development Commissioners to provide for a Chair of Animal Pathology. On the professor being appointed, he would be required to prepare a scheme for the development within the University of the study of the diseases of farm animals. For an approved scheme the Commissioners would be prepared to find a capital sum of about 25,000*l.* for buildings, the sites to be provided by the University. While the Corn Production Acts (Repeal) Act Fund lasts, *i.e.* till about 1927, annually recurring grants for maintenance and research would be met out of that Fund. After the Corn Repeal monies come to an end the Ministry confidently expect to find from other sources money to continue the work. In the event then of the necessary financial provision not being forthcoming, the University would be under no obligation to continue the Institute. Both the Schools of Agriculture and of Medicine stand to gain greatly from this new scheme, and work of the utmost importance for that side of agriculture which depends on live-stock will be initiated.

It is proposed to confer the degree of M.A., *honoris causa*, on Mr. Humphry Gilbert-Carter, director of the Botanic Garden.

LONDON.—A course of four public lectures on "Electric Fields in Atomic Physics" will be given at University College, at 5.15 on March 13, 15, 20, and 22, by Prof. E. T. Whittaker. Admission will be free, without ticket.

Applications are invited by the Senate for the University readership in cultural anthropology tenable at University College. The latest time for the receipt of applications (12 copies) is the first post of Thursday, February 22. They should be sent to the Academic Registrar, University of London, South Kensington, S.W.7.

OXFORD.—An examination will be held at Keble College on March 13 for two science scholarships, each of the annual value of 80*l.*, plus 20*l.* laboratory fees. The subjects of the examination will be chemistry or biology, with elementary physics, and, for biologists, elementary chemistry in addition. Information can be obtained from Dr. Hatchett Jackson, Keble College, Oxford.

Dr. R. A. Peters, lecturer in biochemistry in the University of Cambridge, has been elected to the Whiteley professorship of biochemistry.

DR. G. H. CARPENTER, professor of zoology at the Royal College of Science, Dublin, has been appointed keeper of the Manchester Museum.

DR. RAFFAELE ISSEL, son of the late Prof. Arturo Issel, the geologist, has been appointed professor of zoology in the University of Genoa.

IN the course of the annual dinner of the Honourable Society of Cymmrodorion on January 19, at which the Prince of Wales was the chief guest, Mr. Dan Radcliffe promised, in honour of His Royal Highness, to give 50,000*l.* for the benefit of the University of Wales.

THE Sydney correspondent of the *Chemical Trade Journal* writes that the secretary of the Victorian Chamber of Manufactures has informed the registrar of the University of Melbourne that the sum of 1500*l.* per annum for ten years has been contributed for the University funds "for the purpose of assisting in providing and maintaining professional chairs associated with arts and sciences which have relation to industries and production."

IN connexion with Battersea Polytechnic, Tate scholarships in engineering, science, and domestic science are being offered for competition in June next. The scholarships vary in value from 20*l.* to 30*l.* per annum, with free tuition, and are tenable for two or three years. The latest day for the receipt of applications is April 21. Further particulars are obtainable from the principal.

"THE continued neglect of science as a part of general education in schools" is lamented by the advisory committee on the textile industries and colour chemistry departments of the University of Leeds in a report for the year 1921–22. They are able, nevertheless, to congratulate these departments on being permeated as never before by the spirit of research. An illustrated account of one of their investigations—into the ancestry of the Suffolk Down sheep—appeared early last year in NATURE (vol. 109, p. 595). The number of students, though smaller than in the preceding year, was still large: day students 277, evening 131. More than 80 per cent. of students who completed their course in the department of colour chemistry and dyeing last session obtained either positions in factories or research scholarships; there is evidence of an increasing tendency for large manufacturing firms to engage only those students of the department who have obtained in addition to the honours degree some experience of research in pure science.

A USEFUL "Record of Educational Publications" is issued from time to time by the United States Bureau of Education. Those of May and September 1922 (Bulletins 21 and 33, 5 cents each) covering a period of about 8 months, contain some 800 titles of books and articles classified under such headings as: educational history, current educational conditions, educational theory and practice, educational psychology, psychological tests, etc. In many cases a brief synopsis of the contents is given. Eleven books and pamphlets, containing 1300 pages, and 50 magazine articles are devoted to the subject of intelligence tests, interest in which was greatly stimulated in America by their utilisation during the war for recruiting purposes. Under the heading of higher education appear notices of two works by French "exchange" professors, one being "Universities and Scientific Life in the United States" (Oxford University Press), by M. Caullery, who was exchange professor of biology at Harvard, and one, "Six mois à l'université Yale," by A. Feuillerat, which appeared in the *Revue des deux Mondes* for February and March 1922. *School Life* announces that seven American universities have combined to finance an exchange between Prof. Jacques Cavalier of Toulouse and Prof. A. E. Kennedy of Harvard and the Massachusetts Institute of Technology.

Societies and Academies.

LONDON.

Royal Society, February 1.—O. W. **Richardson**: The magnitude of the gyromagnetic ratio. The gyromagnetic ratio has the value m/e instead of 2m/e, the value calculated on the turning electron orbit theory of magnetism of the Langevin type; the discrepancy may be due to the rotation of the atomic nucleus. In iron it appears that the effective electron orbits possess altogether two quanta of angular momentum per atom and the nucleus a single quantum of angular momentum on this view.—Sir Richard **Paget**: The production of artificial vowel sounds. Plasticene resonators were used to imitate resonances heard by the writer in his own voice when breathing various English sounds. The first models, made in rough imitation of the oral cavity, gave two double resonances. The models were tuned by appropriate alterations of form until they gave recognisable breathed vowel sounds when blown through a small orifice at the back. An artificial larynx was made by means of a rubber strip laid edgewise across a flattened tube, and, when blown through this larynx, the models gave recognisable voiced vowels. The oral cavity behaves in every case as two Helmholtz resonators in series, and the remaining vowel sounds were reproduced by forming two separate resonators joined together in series, and made of such capacity and size of orifices as to allow for mutual reaction of resonators on their respective resonant pitch. Vowels may be produced by two resonators in series with a larynx between them, and a single tubular resonator may act as two resonators in series. Two resonators in parallel, blown by means of a single larynx with a bifurcated passage, produced vowel sounds indistinguishable from resonators in series.—F. **Simeon**: The carbon arc spectrum in the extreme ultra-violet. The arc-spectrum of carbon gives lines in the Lyman region at 1194, 945, 858, 687, 651, 640, 599, and 595, which have not been previously observed. They correspond with prominent lines in the "hot-spark" spectrum studied by Millikan. Groups of lines have been found at 1657, 1560, 1335, 1329, 1260, 1194, 1175, 1036, and 651, of which those at 1329, 1260, 1194, 1036, and 651 do not seem to have been observed by any other worker, and that at 1657 has not been completely resolved heretofore.—J. **Joly**: Pleochroic haloes of various geological ages.—H. A. **Wilson**: The motion of electrons in gases.—H. **Hartridge**: The coincidence method for the wave-length measurement of absorption bands. Measurements of the absorption bands of pigments by the ordinary spectroscope are inaccurate because of the breadth of the bands and the indefiniteness of their margins. The adjustment of two similar absorption bands into coincidence can be effected with considerable accuracy. If then a spectroscope is designed in which two spectra are seen side by side on looking down the eyepiece, but reversed in direction with one another, the measurement of the mean wave-length of the absorption bands can be accurately carried out. The quantitative estimation of pigments depends on the movement of the bands which occurs when the concentration of one pigment changes. In measuring the percentage saturation of blood with carbon monoxide from the wave-length of the *a*-absorption band, the accuracy of measurement is approximately 0·7 A.U. The probable error in setting two absorption bands into coincidence is little greater than that of setting two sharp black lines into coincidence, or of making one line bisect the area between two others.—A. **Berry** and Lorna M. **Swain**: On the steady motion of a cylinder through infinite viscous fluid. The so-

called "inertia" terms are neglected and a solution is found which satisfies the boundary conditions on the cylinder and makes the velocity only logarithmically infinite in one direction at infinity. The relative velocity increases comparatively slowly with the distance from the cylinder, and the solution should give a fairly good approximation to the motion at small distances from the cylinder. First, the elliptic cylinder is treated as a limiting case of the ellipsoid. The solution, which in the case of the ellipsoid satisfies the boundary conditions and those at infinity, leads to a solution for the elliptic cylinder. The plane laminæ, both along and perpendicular to the stream, are considered as limiting cases, and further, the motion due to the circular cylinder is deduced as a special case of the elliptic cylinder. Secondly, the solutions for the elliptic and circular cylinders are obtained directly from the equations of motion. Finally, stream-lines, curves showing variation of velocity along stream-lines and curves of constant velocity are drawn for three limiting cases.—W. **Jevons**: The line spectrum of chlorine in the ultra-violet (Region λ 3354-2070 Å.). Observations of the spectrum of the chlorine discharge tube, which have not hitherto extended lower than λ 3276 Å. (Eder and Valenta), have been continued so far as λ 2070 Å. by means of 10-feet grating and quartz-prism spectrographs. Wave-lengths and wave-numbers of nearly 200 newly observed Cl lines are recorded, together with the effects of variations of capacity on the intensities of more than 100. The constant differences ($\Delta\nu$) 40·4, 67·1, 107·5, found by Paulson in pairs and triplets above λ 3276 Å. recur in a few pairs below that point. The significance of these separations in relation to the analysis of the spectrum, however, appears doubtful, since there is no apparent regularity in the intensities of the lines involved, and no triplets having these separations have been detected in the region under investigation.—M. H. **Evans** and H. J. **George**: Note on the adsorption of gases by solids and the thickness of the adsorbed layer. The amount of carbon dioxide adsorbed by unit surface of glass, at a pressure approximating to one-sixth of an atmosphere, suggests that the carbon dioxide is condensed on the surface of the glass in a liquid layer having a thickness equal to between five and six times the diameter of the molecule of the gas. By combining this result with the published figures of Mülfarth (*Ann. d. Physik*, 1900, vol. 3, p. 328) on the relative adsorption by glass of the gases acetylene, nitrous oxide, carbon dioxide, sulphur dioxide, and ammonia, it is found that these gases are adsorbed by the surface to such an extent that if they were present as liquid layers, the thickness of the layers would vary from (in the case of acetylene) three, to (in the case of ammonia) forty molecular diameters. A direct determination of the degree of adsorption of ammonia gives a value of the same order as that calculated from Mülfarth's data. The results are in disagreement with Langmuir's recent generalisation that the forces of attraction exerted by a surface do not extend to a distance greater than the diameter of one molecule.

Linnean Society, January 18.—Dr. A. Smith Woodward, president, in the chair.—G. H. **Wilkins**: (1) A dried vegetable mass made from a variety of wild plants, Chenopodium and others. The plants are now important in the food-supply of the Russian peasantry; they are dried, pounded to a fine flour, and mixed with rye to make coarse cakes. (2) The Shackleton-Rowett expedition in the *Quest* to the Antarctic Regions. On St. Paul's Rocks no plants save a few Algæ were found, but at South Georgia, an island about 100 miles long and 20 miles broad, a considerable collection was made, and reindeer thrive. Lichens and mosses only were observed on Elephant Island; at Tristan da Cunha 16 species were gathered.—E. G. **Baker**: The flora of Gough Island; 20 flowering plants and 10 ferns are known. The only small trees on the island are Phylica and Sophora. There is a new species of Apium allied to *A. australe* Thouars, but having broad cuneiform segments to the leaves. The widely-spread fern *Lomaria Boryana* Willd. reaches a height of from 2 to 3 feet.—Miss Helena **Bandulska**: The cuticular structure of certain dicotyledonous and coniferous leaves from the Middle Eocene flora of Bournemouth. Three new species of dicotyledonous leaves are described from their cuticular structure. The name Dicotylophyllum is proposed for such leaves of uncertain affinity. The cuticles of some fossil conifers were compared with known recent and fossil forms. Thus *Araucarites Göpperti* Sternberg, *Taxodium europæum* Sap. and *Sequoia Tournalii* Sap. are considered on the evidence of cuticular structure to be specifically distinct.

Aristotelian Society, January 29.—Prof. A. N. Whitehead, president, in the chair.—Rev. Leslie J. **Walker**: A new theory of matter. The general trend of scientific thought seems to indicate a return to the basic principles of the Aristotelian philosophy, a philosophy in which the concept of energy is no less fundamental than it is in modern scientific theory. On the other hand, the atomic theory, the electron theory, and still more especially the quantum theory, would seem to indicate that we shall sooner or later be forced to give up the notion of an infinitely divisible continuum, and to substitute in its place a continuum composed of definite and indivisible units. There was, prior to Aristotle, a theory which treated the continuum as a structure composed of unit-magnitudes in immediate relation or "contact" one with the other. It is possible to develop this theory on Aristotelian lines, taking as the basic assumption that the characteristic of ether-particles is to be in immediate relation with six and only six other particles, and that the characteristic of mass-centres is that they may be in immediate relation with either more or fewer than six other particles, possibly with four as a minimum and eight as a maximum. The primary type of change would thus be a change in the immediate relation of particles one to another, and the primary law governing such change an ever-increasing approximation towards equal distribution of the ether-particles with respect to the mass-centres. The theory gave rise to several features analogous to those which are of primary importance in the electron theory.

EDINBURGH.

Royal Society, January 8.—Lord Salvesen in the chair.—J. S. **Dunkerly**: Encystation and reserve food formation in *Trinema lineare*. The paper showed that the process of conjugation and encystment in the rhizopod, *Trinema lineare*, is followed by nuclear fusion, and the formation of reserve food material in the cyst is apparently due to the activity of the extra-nuclear chromidial mass.—Lancelot **Hogben**: Photo-micrographs were shown illustrating a new technique for removal of the pituitary gland in frogs and toads; also photo-micrographs of changes in melanophore response incident to partial and total extirpation of the gland.

SHEFFIELD.

Society of Glass Technology, January 17.—Prof. W. E. S. Turner, president, in the chair.—W. H. **Hatfield**: Stainless steel, with some consideration of

its application to the glass industry. Stainless steel can now be made direct into castings, into sheet steel which is very malleable—a development of the last two years—and into tubes, so fine that hypodermic needles are now largely made from stainless tubes. Stainless steel contains 12-14 per cent. of chromium. The carbon content varies a little with the different types but is generally about 0·30 per cent. Stainless steels could be made use of in the glass industry on account of their resistance to scaling and strength at high temperatures. Stainless steel has a high tensile strength, a high fatigue range, and can be hardened and tempered. It might be utilised for parison and blow moulds; many parts of feeder devices might be usefully produced in such material, and also blowing irons, rolls, belt conveyors, lehr chain pins, and other things, including knives for cutting viscous glass. The ends of blowpipes might also be made of stainless steel as well as wire brushes. Stainless steel is being used for mirrors for scientific purposes.—S. **English**: Some measurements of the viscosity of glasses near their annealing points and a critical review of some recent literature on the annealing of glass. Strain in glass cannot always be detected by using polarised light; the most sensitive position is that in which the direction of the strain in the glass is at 45° to the plane of polarisation. The selenite plate is more sensitive than plain crossed nicols only when a very poor source of light is used; it is not possible to distinguish between tension and compression stresses by the use of such a plate. The rate of change of mobility of glasses at their annealing points is approximately constant, most requiring a rise of temperature of 9° to cause a doubling of the mobility. In some cases this temperature interval rises to 11°. At 100°-150° above the annealing points the temperature interval required to double the mobility was generally rather longer than that required at the annealing points. The mobility of glasses is not a logarithmic function of the temperature. The working properties of lead glasses and other soft glasses are probably determined more by the rate of radiation of heat than by rate of change of viscosity with temperature.

PARIS.

Academy of Sciences, January 15.—M. Albin Haller in the chair.—The president announced the death of M. van de Sande Bakhuyzen, corresponding member for the section of astronomy.—L. **Lindet** and P. **Nottin**: The evolution of the starch grains in the tuber of the potato.—W. **Kilian** and F. **Blanchet**: The ammonites collected by the *Pourquoi-Pas?* Emmanuel de Margerie was elected corresponding member for the section of mineralogy in the place of the late M. Œhlert.—Martin **Ålander**: Integral functions which have all their zeros on a straight line.—G. **Sagnac**: The periodic variable spectrum of double stars: the incompatibility of the observed phenomena with the theory of general relativity.—J. **Haag**: The problem of *n*-bodies in the theory of relativity.—Edouard and Rémy **Urbain**: The separation of liquid mixtures by combined distillation and atmolysis. The preparation of practically pure ethyl alcohol and nitric acid. The alcohol is boiled in a flask fitted with a porous tube as reflux condenser. Round this tube is an outer glass tube in which the pressure is reduced. More water than alcohol vapour diffuses through the porous tube, and the alcohol in the flask can be strengthened to 99·8 per cent.—Ch. **Bedel**: A polymer of hydrocyanic acid. The crude polymerisation product of hydrocyanic acid is extracted with ether, and the brown crystals deposited by this solution purified by solution in hot water and treatment with animal charcoal. Its composition is $(HCN)_4$ and appears to be aminopropanedenitrile hydrocyanide.—Alfred **Schoep**: Parsonite, a new radioactive mineral. This is found associated with chalcolite from the Belgian Congo; and has the composition $2PbO.UO_3.P_2O_5.H_2O$. It is radioactive.—Mlle. Germaine **Cousin**: The prolongation between Belfort and Thann of the tectonic accidents of the secondary border situated to the south of the Vosges *massif*.—Ch. **Dufour**: Values of the magnetic elements at the station of Val-Joyeux (Seine-et-Oise) on January 1, 1923.—Odon **de Buen** and José **Giral**: The hydrographic tables of Knüdsen, normal water and the limits of error in the analysis of sea water.—Louis **Besson**: The loss of light in Paris and its neighbourhood. Curves are given showing the proportion of light received at nine observing stations as a function of the direction of the prevailing wind.—G. **Mangenot**: The starch of the red Algæ.—A. **de Puymaly**: New mode of cell division in the Desmidaceæ.—Emile **Haas**: New experiments on the phenomenon of Broca and Sulzer (fatigue undulation).—A. **Goris** and A. **Liot**: The importance of organic ammoniacal salts in the production of pyocyanine by the pyocyanic bacillus.—J. P. **Aversenq**, L. **Jaloustre**, and E. **Maurin**: Some effects of thorium-X on diastases and micro-organisms. Thorium-X clearly increases the activity of the hydrolysing or oxidising properties of the enzymes studied (pyalin, amylase from pancreatic juice, amylase from germinated barley, emulsion, ammonia ferment, oxydases of the blood and saliva), and also increases the vitality of certain pathogenic organisms.—Georges **Bourgignon** and Henri **Laugier**: Variations of the neuromuscular excitability under the influence of the suppression and re-establishment of the circulation of a limb in man.

WASHINGTON.

National Academy of Sciences (Proc. vol. 8, No. 12, December 1922).—O. **Veblen**.—Projective and affine geometry of paths.—W. F. **Hamilton**: A direct method of testing colour vision in lower animals. Two Hilger wave-length spectrometers used as monochromatic illuminators were arranged to throw beams of light on the opposite ends of a horizontal glass tubular cell containing Drosophila which had been kept in the dark overnight. The intensities of the beams (of different wave-lengths) were regulated so that the flies showed no orientation. One beam was then screened for a time, and on again exposing it, the flies definitely moved towards it showing differential fatigue. The smallest difference of wave-lengths showing a stimulating effect was used, and over the range 385-500 $m\mu$, hue-perception is a maximum between 410 $m\mu$ and 450 $m\mu$, possibly indicating two receptor systems, one for the blue-violet and one for the blue-green.—L. L. **Nettleton**: Characteristics of a short wave oscillator at very low pressures. A three-element tube was left permanently connected with the vacuum pumps, and currents up to 300 milliamps. at 700 volts were used. The oscillations were measured by a crossed wire thermocouple carried on a bridge sliding along the Lecher wires. Oscillations of wave-length 50-200 cm. were obtained. Both negative plate current and oscillations ceased abruptly at very low pressures (0·00005 mm.) in the tube as measured by an ionisation manometer. The curves resulting from plotting the voltage at the plate and the oscillations in the Lecher wires against the ionisation appear to show that some little ionisation is necessary for this type of oscillation, but the kind of gas present does not seem important.—Bergen **Davis** and H. M. **Terrill**. The refraction of X-rays in calcite. A water-cooled tube with a molybdenum target was used and measurements were made for the first three orders of the $K\alpha_1$

line. The results correspond to a shift of the first order line of 5″, so for this wave-length, the effect of refraction is slight. P. W. Bridgman.—The compressibility of metals at high pressures. The pressure range was 12,000 kgrm./cm.², and measurements were made at 30° and 75°. The compressibility of every metal decreases with rising pressure and, generally, increases with rising temperature; the order of magnitude of the change is the same for all the metals. Germanium and uranium are possible exceptions. Metals crystallising in a cubic form show the same compressibility in all directions, but the compressibility of, *e.g.*, zinc, measured in three directions perpendicular to each other, varied in the order, roughly, of 1 : 3 : 4. Tellurium shows a negative effect in one direction. The results accord with a theory of two interpenetrating lattices as the structural basis of most metals. There appears to be no simple repulsive potential relation between the atoms of metals which will account for the compressibility data.—Raymond Pearl and L. J. Reed: A further note on the mathematical theory of population growth.

Official Publications Received.

Annual Report of the Meteorological Committee to the Air Council, for the Year ended 31st March 1922. (M.O. 257.) Pp. 59. (London: H.M. Stationery Office.) 2*s.* net.

Ministry of Finance, Egypt: Coastguards and Fisheries Service. Report on the Fisheries of Egypt for the Year 1921. By G. W. Paget. Pp. vi+78. (Cairo: Government Publications Office.) P.T.5.

Catalogue of the British Industries Fair, The White City, Shepherds Bush, London, W.12, February 19–March 2, 1923. Pp. xxxii+256+180. (London: Board of Trade.) 1*s.*

Air Ministry: Meteorological Office, London. Southport Auxiliary Observatory (The Fernley Observatory of the Corporation of Southport). Annual Report, and Results of Meteorological Observations, for the Year 1921; with an Appendix containing Monthly Averages, for 10 years, of the Amount and Duration of Rainfall under Different Wind Directions. By Joseph Baxendell. Pp. 36. (Southport: Fernley Observatory; London: Meteorological Office.)

Diary of Societies.

MONDAY, FEBRUARY 12.

ROYAL SOCIETY OF MEDICINE (War Section), at 5.—Surg. Comdr. R. J. M'Keown and Surg. Comdr. A. Gaskell: The co-operation between the Members of the profession and the medical services of the armed forces in peace and during war.—Discussion: Air Commodore D. Munro, Major-General C. E. Pollock, and others.

ROYAL SOCIETY OF ARTS, at 8.—Dr. H. P. Stevens: The Vulcanisation of Rubber (Cantor Lectures) (2).

SURVEYORS' INSTITUTION, at 8.—C. P. Sanger: The Law of Property Act, 1922.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—H. St. J. B. Philby: The North Arabian Desert.—Major A. L. Holt: The Future of the Desert.

MEDICAL SOCIETY OF LONDON, at 8.30.—Dr. E. F. Buzzard and others: Discussion on Psycho-Therapeutics.

TUESDAY, FEBRUARY 13.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. C. Pearson: Greek Civilisation and To-day (1): The Beginnings of Science.

ROYAL SOCIETY OF MEDICINE (Therapeutics and Pharmacology Section), at 4.30.—Prof. A. J. Clark: The Scientific Basis of Non-Specific Protein Therapy.—Dr. H. Blumgart: The Treatment of Diabetes Insipidus by Intra-Nasal Spraying of Pituitary Extract.

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.—G. W. E. Gibson: Some Practical Notes on Oil Pumping.

BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (at London Day Training College), at 6.—Miss Ella Freeman Sharpe: The Super-sensitive Child at School. A Psycho-Analytic Study.

INSTITUTE OF TRANSPORT (at Institution of Electrical Engineers), at 6.—B. Wagenrieder: Railway Rules and Regulations.

INSTITUTE OF MARINE ENGINEERS, INC., at 6.30.—T. D. Madsen: Internal Combustion and Economy.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Scientific and Technical Group), at 7.—A. E. Bawtree: Dangers to Eyesight in Domestic Electric Lighting and the Kinema Picture Display.

QUEKETT MICROSCOPICAL CLUB, at 7.30.—D. T. Scourfield: Presidential Address.

INSTITUTE OF INDUSTRIAL ADMINISTRATION (at London School of Economics), at 8.—F. Mott: Practical Hints on Buying and Selling. (To be followed by a Discussion.)

ROYAL SOCIETY OF MEDICINE (Psychiatry Section), at 8.30.—Dr. K. Wilson: Involuntary Laughing and Crying.

WEDNESDAY, FEBRUARY 14.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 4.—Sir John Bland-Sutton: Hunterian Oration.

ROYAL SOCIETY OF MEDICINE (Surgery: Sub-section of Proctology), at 5.30.—P. Lockhart-Mummery: New Method of treating Ischio-Rectal and other Abscesses.

INSTITUTION OF AUTOMOBILE ENGINEERS, at 7.30.—J. L. Chaloner: High-speed Oil Engines.

ASSOCIATION OF ENGINEERS-IN-CHARGE (at St. Bride's Institute), at 7.30.—C. H. J. Day: Hydraulic and Electric Lifts.

ROYAL SOCIETY OF ARTS, at 8.—W. J. Rees: Progress in the Manufacture of Refractories.

THURSDAY, FEBRUARY 15.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. B. Melvill Jones: Recent Experiments in Aerial Surveying (1).

ROYAL SOCIETY, at 4.30.—E. R. Speyer: Researches upon the Larch Chermes (*Cnaphalodes strobilobius*, Kalt) and their bearing upon the Evolution of the Chermesinæ in general.—G. V. Anrep: The Irradiation of conditioned Reflexes.—M. Dixon and H. E. Tunnicliffe: The Oxidation of reduced Glutathione and other Sulphydryl Compounds.—J. C. Bramwell, R. J. S. M'Dowall, and B. A. M'Swiney: The Variation of Arterial Elasticity with Blood Pressure in Man.—L. J. Harris: The Existence of an undiscovered Sulphur Grouping in the Protein Molecule. Part I. The Denaturation of Proteins. Part II. The Estimation of Cystine in certain Proteins.—N. B. Laughton: Reflex Contractions of the Cruralis Muscle in the Decerebrate and Spinal Frog.

LINNEAN SOCIETY OF LONDON, at 5.—A. M. Altson: On the Method of Oviposition and the Egg of the Beetle *Lyctus brunneus*, Steph.—R. Paulson: Arctic Lichens from Spitsbergen.—F. H. Lancum: Strange Behaviour of a Female Butterfly, *Colias edusa*.—Canon Bullock-Webster: Exhibition of Thirty Varieties of *Chara hispida*.

ROYAL SOCIETY OF MEDICINE (Dermatology Section), at 5.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 5.30.—Wing-Commdr. T. R. Cave-Brown-Cave: The Practical Aspects of the Seaplane.

INSTITUTION OF MINING AND METALLURGY (at Geological Society), at 5.30.

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Miss Richardson: M. Coué and his Work.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—J. Rosen: Some Problems in High-speed Alternators and their Solution.

CHEMICAL SOCIETY, at 8.—A. Chaston Chapman: Spinacene, its Oxidation and Decomposition.—R. H. Pickard and H. Hunter: Investigations on the Dependence of Rotatory Power on Chemical Constitution. Part XIX. The Rotatory and Refractive Dispersion of *d*-γ-nonyl nitrite.—H. Hunter: Investigations on the Dependence of Rotatory Power on Chemical Constitution. Part XX. The Rotatory Dispersive Powers of Oxygen Compounds containing the Secondary Octyl Radicle.

CAMERA CLUB, at 8.15.—Major F. C. B. Laws: Progress in Aerial Photography.

FRIDAY, FEBRUARY 16.

GEOLOGICAL SOCIETY OF LONDON, at 3.—Annual General Meeting.

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.—J. T. Marten: The Indian Census, 1921.

ROYAL SOCIETY OF MEDICINE (Otology Section), at 5.—G. J. Jenkins: Preliminary communication on Osteitis Deformans and Otosclerosis.

INSTITUTION OF MECHANICAL ENGINEERS (Annual General Meeting), at 6.—H. C. Young: Some Mechanical Problems in the Rubber Industry.

INSTITUTION OF ENGINEERING INSPECTION (at Royal Society of Arts), at 7.30.—H. T. F. Rhodes: Chemical Inspection as it is and as it should be.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—T. L. Allison: Notes on some Insulating Materials.

EUGENICS EDUCATION SOCIETY (at Prince's Restaurant), at 7.30.—Prof. Pigou: The Economic Importance of Eugenics.

ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section), at 8.30.—Prof. Philippson: High-frequency Currents applied to the Study of Cellular Physiology.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. A. V. Hill: Muscular Exercise.

SATURDAY, FEBRUARY 17.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Ernest Rutherford: Atomic Projectiles and their Properties (1).

PUBLIC LECTURES.

SATURDAY, FEBRUARY 10.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—E. Lovett: Household Appliances of a Hundred Years Ago.

TUESDAY, FEBRUARY 13.

GRESHAM COLLEGE, at 6.—Sir Frederick Bridge: Music. (Succeeding Lectures on February 14, 15, and 16.)

WEDNESDAY, FEBRUARY 14.

UNIVERSITY COLLEGE, at 5.—P. Leon: The Theory of Beauty. (Succeeding Lectures on February 21, 28, March 7, 14, and 21.)

KING'S COLLEGE, at 5.30.—Dr. D. H. Scott: The Succession of Floras in the Past.

FRIDAY, FEBRUARY 16.

LONDON SCHOOL OF ECONOMICS, at 5.—Prof. Graham Wallas: The Competition of the Sexes for Employment (Stansfeld Lecture).

UNIVERSITY COLLEGE, at 5.15.—P. A. Scholes: The Place of Music in the Education of the Future.

KING'S COLLEGE, at 5.30.—Dr. E. W. Scripture: Shakespeare's Verse in the Light of Experimental Phonetics.

SATURDAY, FEBRUARY 17.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Dr. F. A. Bather: A Limestone Cliff and the Animals that built it.

NEGRETTI & ZAMBRA
38, HOLBORN VIADUCT, E.C.1.
LONDON.

UNIVERSITY OF LONDON.

A Course of three Lectures in Zoology (with lantern illustrations) on "THE BIONOMICS OF MARINE ANIMALS" will be given by DR. J. H. ORTON, D.Sc. (of the Marine Biological Association, Plymouth), at KING'S COLLEGE, LONDON (Strand, W.C.2), on TUESDAY, February 20, THURSDAY, February 22, and FRIDAY, February 23, 1923, at 5.15 P.M. At the first Lecture the Chair will be taken by Prof. ARTHUR DENDY, F.R.S. (Professor of Zoology in the University). ADMISSION FREE, WITHOUT TICKET.

EDWIN DELLER, Academic Registrar.

KEBLE COLLEGE, OXFORD.

NATURAL SCIENCE SCHOLARSHIP, 1923.

An Examination will be held in this College on March 13 for two SCIENCE SCHOLARSHIPS of the annual value of £80, with laboratory fees £20.

Subjects: Chemistry *or* Biology, with elementary Physics, and for Biologists elementary Chemistry as well.

Intending candidates should apply to Dr. HATCHETT JACKSON, the Science Tutor, for information.

BATTERSEA POLYTECHNIC

LONDON, S.W.11

Award of Tate Scholarships for Session 1923-24.

The examinations for the award of SCHOLARSHIPS in ENGINEERING, SCIENCE, and DOMESTIC SCIENCE, will be held on Tuesday, June 5, 1923, and the succeeding days. The scholarships vary in value from £20 to £30 per annum with free tuition, and are tenable for two or three years.

Last day of entry April 21, 1923.

Full particulars on application to the PRINCIPAL.

RESEARCH FELLOWSHIPS IN ACOUSTICS.

THE RIVERBANK LABORATORIES AT GENEVA, ILLINOIS, announce the establishment of one or two RESEARCH FELLOWSHIPS in ACOUSTICS. The holder will have an opportunity to devote his entire time to study and investigation in a laboratory built, equipped, and manned for the study of acoustic problems. Candidates should be college graduates who have taken advanced courses in physics and mathematics, and who have shown in their work those qualities essential for success in independent investigation. Terms of appointment to be determined by the qualifications of the appointee. Address, B. CUMMING, Secretary, Geneva, Illinois.

THERESA SEESSEL RESEARCH FELLOWSHIP

To promote Original Research in Biological Studies.

YALE UNIVERSITY.

One FELLOWSHIP, yielding an income of $1500. Preference is given to candidates who have already obtained their Doctorate, and have demonstrated by their work fitness to carry on successfully original research of a high order. The holder must reside in New Haven during the college year, October to June. Applications should be made to the DEAN of the GRADUATE SCHOOL, New Haven, Conn., before May 1, 1923; they should be accompanied by reprints of scientific publications, letters of recommendation, and a statement of the particular problem which the candidate expects to investigate.

NATIONAL UNION OF SCIENTIFIC WORKERS.

THE AIM OF THE NATIONAL UNION OF SCIENTIFIC WORKERS is to bring together into one professional organisation all qualified scientific workers, viz.:

Those engaged (*a*) In Higher Educational and Research Institutions.
(*b*) In Industry and Consultative Practice.
(*c*) In State and Municipal Scientific Departments.

Applications for membership are invited from all scientific workers with university degree or equivalent professional qualification. Further particulars may be obtained from

THE GENERAL SECRETARY, N.U.S.W.,
25 Victoria Street, S.W.1.

CHELSEA POLYTECHNIC,

CHELSEA, S.W.3.

Day and Evening Courses in Science under Recognised Teachers of London University.

I. **INDUSTRIAL CHEMISTRY DEPARTMENT.** Technical Courses in Analytical and Manufacturing Chemistry, Pharmacy, Food and Drugs, A.I.C. Courses, Metallurgy, Assaying, Foundry Work, Research.

II. **INDUSTRIAL PHYSICS DEPARTMENT.** Practical work in General Physics, Applications to Industries, Metrology, Calorimetry, Illumination, Acoustics, Electrical Measurement. Research.

III. **BIOLOGICAL AND GEOLOGICAL DEPARTMENT.** Courses for B.Sc., etc., in Botany, Geology, Mineralogy, Zoology, Special Courses in Bio-chemistry, Bio-physics, Bacteriology, Physiology, Hygiene, Entomology, Plant Pathology. Course for Tropical Planters, Research.

Telephone: Kensington 809.

SIDNEY SKINNER, M.A.,
Principal.

BATTERSEA POLYTECHNIC.

LONDON, S.W.11.

Principal—ROBERT H. PICKARD, D.Sc., F.R.S.

COURSES FOR WOMEN.

Full-time day courses for women preparing to be teachers of Domestic Subjects.

Preparation for posts as Institutional Matrons and Housekeepers and for colonial and home life.

Full-time day courses of training for Women Health Visitors and Infant Welfare Workers.

Evening courses of training for Sanitary Inspectors, Health Visitors, Meat and Food Inspectors, Smoke Inspectors, etc.

Day and Evening courses in Art, Music, and Domestic Science.

Hostels for Women Students. Large Athletic Ground and numerous clubs and societies.

UNIVERSITY OF SYDNEY, NEW SOUTH WALES.

PROFESSORSHIP OF PHYSICS.

The Senate of the University of Sydney invites application for the CHAIR of PHYSICS, to which is attached a salary of £1100 per annum together with rights to a pension of £400 per annum on certain conditions. The Professor appointed will be expected to enter on his duties on August 1, 1923; £150 will be allowed for travelling expenses from Europe.

Further details concerning the appointment may be obtained on written request to THE AGENT-GENERAL FOR NEW SOUTH WALES, AUSTRALIA HOUSE, STRAND, LONDON, W.C.2, to whom applications for the position, in sextuplicate, accompanied by copies of testimonials (if any), should be sent so as to reach him not later than Wednesday, FEBRUARY 28, 1923. There is no special form of application. All correspondence addressed to the Agent-General in connection with the appointment should be marked on the outside of the envelope "University of Sydney."

London, January 30, 1923.

T. A. COGHLAN,
Agent-General for New South Wales.

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH.

A JUNIOR ASSISTANT CHEMIST is required for the Fuel Research Station, East Greenwich, S.E.10.

Candidates must be honours graduates in Chemistry.

Scale of salary £160—10—£220 per annum plus bonus at the usual Civil Service rates; commencing pay at rates now in force £264:11s., but the rate will be revised on March 1 next. Superannuation provision will be made under the Federated Superannuation System for Universities, under which a contribution of approximately 10 per cent of salary is paid by the Department and 5 per cent is paid by the officer.

Preference will be given, other things being equal, to ex-service men.

Applications giving particulars of age, qualifications, military service, etc., and enclosing copies of testimonials or names of referees should be made in writing not later than February 26 to SECRETARY, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1.

The Social Influence of Science.

SOME controversy has taken place lately as to the part played by science in promoting social progress, and an American book appeared in the autumn specially contesting any such claim. The argument is difficult to follow. To those who take a broad view of history it seems obvious that the growing stability of societies, the wider organisation of all kinds of human activities, the quicker transport and closer communication between nations, are all due mainly to the spread of science. To those who look critically at details it seems doubtful whether our societies are really stable, whether life is now happier or nobler than it was in less scientific days, whether the evils and destruction wrought by modern instruments do not outweigh the undoubted advantages that science has brought.

Our judgment in this great debate will be dictated largely by our temperament. The critical, the melancholy, the disappointed will be inclined to think that the rush, the complexity, the vastness of the modern world have brought more evils than they have removed. The young and vigorous, those who enjoy life and hope for its continuance, will take another view, and these, with the improvement in health which still goes on and the increase in prosperity which was continuous until the war, form a large normal majority. The current depression of spirits, which is not perhaps so widespread as is commonly supposed, is due partly to a reaction against the exaggerated optimism of the Victorian age, partly to the troubles due to the war. It ought to be possible to put aside these disturbing influences and take a broad calm view of social progress. In any such survey the influence of science in recent centuries is necessarily a leading feature.

Now the first condition of such a review is to make it wide enough. The processes of life develop by minute changes, and when a violent change does occur, it has to be readjusted and equilibrium set up again by counterbalancing changes. Hence it would be a gross distortion of the truth to judge—and condemn—the industrial revolution by comparing peaceful rural England with the horrors of the early years of the factory system. The latter were new and unforeseen facts which called for special remedial measures. It is equally absurd at the present day to declare modern civilisation bankrupt because the German financial system has broken down and no one has yet seen how to re-establish international trade and credit. These things are momentary, unexpected shocks: the world has passed through far worse storms in its time and we shall weather the less as we have the greater. A sound judgment can be based only on a wide view, and in a matter so vast as social progress affected by science,

the view should be as extensive as the subject itself.

People have lately been using the term "science" in a looser and more comprehensive sense than heretofore. Its roots might be found in the practical skill, the mother-wit and sharp senses of the primitive savage. In any case the beginnings may be seen in the settled communities of the great river-valleys, in Egypt, Babylonia, the Yangtze, as well as in Mexico and Crete. Can one doubt that the science involved in the drawing up of the first calendars by the priests of Egypt and in the marvellous structure of the pyramids was a factor of the first importance in preserving the social order and cohesion of those early theocracies, the first great permanent aggregations of mankind upon the planet? The power of prediction involved in science, and first exemplified in the making of the calendar, was intimately bound up with the power of securing obedience, and the acceptance of their lot by the millions who worshipped the Pharaoh.

The Greeks were, of course, the founders of science in the stricter sense, which seeks the law of change, the principle of unity in the manifold; and it might be thought that the constant disunion of ancient Greece disproved the social or unifying effect of science. But this would be to take a narrow and short-sighted view. Greek science had from the first a strong social value. It formed a link between the early philosophers in the Ionian cities of its birth, and in the case of the Pythagoreans it was the basis of a brotherhood which aimed as much, or more, at social reformation than it did at increasing the scope of abstract thought. In fact all the early Greek philosophers were also interested in social and political problems. They saw that true wisdom was a practical thing, fit to inspire, as Anaxagoras said, "a calm religion free from fear."

But the chief moral and social effect of Greek science came later, first, when Hellenism was spread over the Middle East by the arms of Alexander, secondly, when, in the Greco-Roman world, Greek science and Roman law combined to lay the foundation for the medieval and modern world. The younger Pliny, when proconsul in Asia Minor under Trajan, gives an interesting illustration. He points to the effect of astronomy in allaying the fears and composing the minds of the mass of the people.

In estimating the social influence of science, however, the mind turns naturally to its greatest expansion in the last few centuries. When in the sixteenth century the mind of Ancient Greece awoke again and men began to seek in Nature herself for the answer to the problems of life, there were two new factors in the world which affected the results of their inquiries. One was the discovery of new lands, the expansion of the West. The other was the decay of slavery, the recognition of manual and mechanical work as a worthy occupation of good brains. This the Greeks had never recognised, and their failure limited the application of science to industry in ancient times. But with the advent of a New World and a new spirit in industry, from the sixteenth century onwards, the transformation of society by science went on apace. From the middle of the eighteenth century it has become apparent as the dominating force in the world.

Hence the question of the intrinsic value and the social influence of science is primarily a discussion of the effects of the Industrial Revolution in which we still live. The fact that we are living in it now and making it more complete every moment, adds enormously to the difficulty of valuation. It is a part of ourselves and influences almost every act and thought, and therefore to deplore and condemn the tendency, or to wish it away as Ruskin did, is futile in practice and pessimistic in philosophy.

Two or three main points stand out clear in the contemporary picture. They are, in the first place, facts with which the student of social life has to concern himself to understand the movement; and, in the second place, guides to action, indicating the line which those must take who are pressing for the stability and betterment of society.

The world is one in a new—if you will, an artificial—sense, due to the application of science to transport and communications of all kinds. This process is being accelerated by every possible means and is pre-eminently a social one. It must find its issue in complete international trade and a really comprehensive League of Nations, acting as the organ of common interests and opinion. It is most important to remember that the League of Nations, which we already possess, is the fruit of the historical evolution due to science and was only precipitated and not caused by the war. The unification of the whole world is only the result on a large scale of a process which has knit up every particular society in a closer organisation than before. Science, being itself a social product, due to the intercourse of active minds, finds its expression in a social organisation impossible without the application of science. This is seen not only in the organisation of industry but also in every activity of the community from the government downwards. All are closer and more complicated, just in proportion to the extent that the given society has created, imbibed, and applied the results of scientific thinking. Expressed briefly and broadly, but with perfect truth, humanity is the counterpart of science, the practical obverse of the abstract reverse of thought.

To make this process more effective by conscious

effort is therefore the supreme task of those concerned in social progress at the present time. The growth has hitherto been mainly automatic. We have to understand it, grasp it, and turn it to the still greater good of mankind. Science having made the modern world, with all its strength and its weaknesses, let men of science inspire a social will into the whole community, to use this master-instrument for its highest end, the salvation and elevation of the humanity to which it belongs. F. S. MARVIN.

Phantasms of the Living.

Proceedings of the Society for Psychical Research. Vol. 33, Part 86, October. (London: F. Edwards; Glasgow: MacLehose, Jackson and Co., 1922.) 16*s.* 6*d.* net.

A BOOK entitled "Phantasms of the Living," by Edmund Gurney, F. W. H. Myers, and Frank Podmore, was published in 1886. Under this title were included all experiences where there was reason to suppose that the mind of one living person had affected the mind of another otherwise than through the recognised channels of sense. The chief aim of this book was to produce a cumulative quasi-statistical proof of telepathy.

In the thirty-six years which have elapsed since the publication of this book the Society for Psychical Research has received and published in its Journal many accounts of happenings similar to those recorded by Gurney, and in its Proceedings of October last Mrs. Henry Sidgwick has submitted the best of these cases to a careful examination and analysis.

While Gurney and his collaborators were chiefly concerned to prove telepathy to be a fact of Nature, Mrs. Sidgwick thinks we have arrived at a stage when, if our knowledge of telepathy is to grow, we must seek light on its process and the conditions under which evidence of it can be obtained. She says: "We may now, for the sake of argument at least, assume that Gurney's book has accomplished its object, and that telepathy is proved, and starting from that point may devote ourselves primarily to seeking for light on the occasions and mode of its operation." Mrs. Sidgwick does not mean to imply that telepathy is yet accepted by the scientific world; but she thinks something more than the mere piling up of facts is required, and that "our facts will be the more readily accepted, the more we can compare them, and, provisionally assuming telepathy, show when and how it occurs."

Many of the best cases received by the Society during the past thirty-six years have already been published in various works on psychical research, and fifty-four have appeared in the Proceedings of the Society for Psychical Research. All these, being therefore already before the public, are excluded from this collection. The cases included have appeared only in the Journal of the Society, which is printed for private circulation among members. The value of the present collection is considerably diminished by the exclusion of so many cases which were of course selected for earlier publication, because they were regarded as being specially important or interesting. Even without these, however, we have here some two hundred cases, many of which are important as affording evidence that telepathy does occur, and all of which help to throw some light on the occasions and mode of its operations.

The broad lines of classification adopted in the description of telepathic phenomena may be gathered from the headings of the four chapters into which Mrs. Sidgwick's volume is divided: (1) Experimental and semi-experimental cases; (2) Spontaneous cases in which the percipient's impression is not externalised; (3) Spontaneous cases in which the percipient's impression is externalised as a waking hallucination; also dreams of the same character; (4) Collective and reciprocal cases without evidence of any agency external to the percipient.

In all modern records of telepathic experiences the person whose mind receives the impression is called the percipient, and the person from whose mind the impression comes is called the agent; but it would appear from the evidence that the percipient is very often the "active" party, and that the so-called agent plays a purely passive part. This is seen in the semi-experimental cases in which a percipient is trying to get an impression from another person who is quite unaware that any such attempt is being made. In experimental cases, properly so-called, the agent is deliberately trying to impress telepathically a particular percipient, and that percipient is deliberately trying to receive an impression. It is doubtful, however, what part, if any, the concentrated effort of the agent plays in the success of such experiments.

The experimental and semi-experimental cases recorded in this collection can scarcely be regarded as representative of the group because of the number excluded, owing to their having been already published; but even had these been included there would still have been occasion for Mrs. Sidgwick's comment that "more experiments carefully conducted and well recorded are greatly needed."

Of spontaneous cases in which the percipient's impression is not externalised as a hallucination, Mrs. Sidgwick says: "As a whole the class is not a strong one as evidence of telepathy," because the triviality or vagueness of the impression in many cases makes

tricks of memory very likely to occur. Of more importance as providing evidence of the occurrence of telepathy are the spontaneous cases in which the percipient's impression is externalised as a waking hallucination. The first case recorded under this heading (p. 152) is one of the most striking in the whole collection. It is one of the many cases of "death coincidences" which form an important part of the evidence for telepathy. (Apparitions or other hallucinatory experiences occurring within twelve hours of the death, before or after it, are classed as phantasms of the living.) The apparition in this case was that of an officer of the Royal Air Force, who was killed in a flying accident on December 7, 1918, and the percipient was a fellow-officer who spoke of his experience to another person before it was realised that it was not the living man who had appeared.

Another interesting case in this section is a dream experience, first recorded in the *Times* of July 21, 1904, by Mr. Rider Haggard, the percipient (p. 219). The dream was to the effect that a favourite retriever dog was lying on its side among brushwood, or rough growth of some sort, by water. The recorder says: "In my vision the dog was trying to speak to me in words, and, failing, transmitted to my mind in an undefined fashion the knowledge that he was dying." Investigation showed that the dog had been killed by a passing train, and had fallen into a stream where reeds grew, at or about the time of the dream experience. The case is well authenticated, and all the circumstances point to the improbability that "mere coincidence" is the true explanation. Another striking case is one reported by Sir George Beilby (p. 243), in which a percipient had a visual hallucination of her brother in Australia at a time when he had fallen into unconsciousness which lasted until his death some days later.

"Collective and reciprocal cases" are dealt with by Mrs. Sidgwick in her final chapter. These are cases in which "two or more persons have at the same time spontaneous psychical experiences—either hallucinations or dreams—which seem to be related to one another, but where no evidence of any agency outside the two percipients exists." When the percipients were in the same room we must consider the possibility that one percipient may have influenced the other through the senses (suggestion), but where the percipients were in different rooms or in different houses, the relation of the one hallucinatory or dream experience to the other can scarcely be accounted for in this way. Here either chance or telepathy must be invoked.

In concluding her examination of this collection of phantasms of the living, Mrs. Sidgwick describes two cases of reciprocal dreams, in both of which the dreamers were in separate houses, and in both of which the reciprocality seems to have been very complete. Reciprocal cases are rare, and the small number recorded hitherto has raised some doubts as to the genuineness of the type; but Mrs. Sidgwick thinks they are very important as throwing light on the whole process of telepathic communication. She says: "I think the kind of union of minds, the thinking and feeling together, here shown, may be regarded as the type or norm of telepathic communication to which all other cases conform in varying degrees." This implies a merging together of minds, a "transfusion" of thought rather than a transmission or transference. We have the physical analogy of "contact" in place of "transmission-through-space."

It can scarcely be maintained that the cases here passed in review afford by themselves very strong proof of the occurrence of telepathy, but taken in conjunction with the body of evidence brought forward by Gurney, and the many well-attested cases published in the Proceedings of the Society for Psychical Research and elsewhere, they help to strengthen the conviction, to which many competent observers have been forced, that these accounts of apparent action of mind upon mind in the absence of any physical medium of communication, bring to our notice some fact of Nature which students of science can no longer ignore.

The most obvious, and perhaps the most serious defect in the evidence for telepathy afforded by these cases is the long interval which so frequently elapsed between the experience and the recording of it. In only 11 out of 191 tabulated cases was the record made on the day of the experience, and 4 of these were semi-experimental cases, in which one might have supposed immediate record to have been a necessary part of the experiment. In 15 instances the record was made "next day." In most of the cases the interval extended for months or years, but all cases in which it exceeded five years are omitted from this collection.

After all that has been written about the importance of immediate record and attestation of any presumably super-normal experience, it is astonishing that those who are subject to such experiences should so often neglect this elementary rule. T. W. MITCHELL.

The Synthetic Colour Industry.

The Manufacture of Dyes. By Dr. John Cannell Cain. Pp. ix+274. (London: Macmillan and Co., Ltd., 1922.) 12*s.* 6*d.* net.

THE author of this treatise, which is published posthumously, was one of a small band of British chemists, who long before the war placed their

services at the disposal of the home industry in synthetic dyes. But, largely owing to lack of appreciation of the value of scientific knowledge on the part of manufacturers, the result in almost all cases was disillusionment and disappointment, so that this group of trained investigators, including Dr. Cain, were compelled by force of adverse circumstances to transfer their activities to other branches of chemical enterprise. In 1915, however, the Government became aware somewhat tardily of our national deficiencies in regard to the manufacture of dyewares, and Dr. Cain was appointed a member of the technical committee of British Dyes, Limited, afterwards holding the position of chief chemist in the newly erected Dalton works of this firm. His experiences in these two phases of the English colour trade, extending over twenty-five years, are embodied in the manual under review.

It is obvious that in a handbook of some 260 pages all the important colouring matters cannot be included, and among the notable omissions are such well-known synthetic dyes as the Hessian purples, formyl violet, rhodamine S, the acridine yellows, and the first representatives of the anthraquinone vat dyes, namely, indanthrene blue and yellow. Nevertheless, a judicious and typical selection has been made, and the author has given full working details wherever he has possessed first-hand practical knowledge of the factory operations.

This impress of realism is especially noticeable in the informative chapters on azo and triphenylmethane dyes; for in both these branches of colour production Dr. Cain ranked as an expert. As, however, this work will be read by students, it is perhaps permissible to point out that the somewhat unnecessary rubrics at the beginnings of the chapters on monoazo and disazo dyes do not tally with the arrangement adopted in the text. Fast red B contains two naphthalene nuclei, although classed as a mixed benzene-naphthalene dye, and diamond black F, placed in the purely naphthalenoid section, contains a benzene nucleus, and there are several other similar discrepancies in classification. In a future edition these headings might with advantage be omitted.

In spite of the apathy prevailing before the war in this branch of chemical industry, British chemists had developed a sound technique in the manufacture of certain standard dyes such as magentas, aniline blues, and safranines. The manual contains useful information in regard to these intricate preparations. On the theoretical side it will be noticed that the author has not adopted the prevailing view that the oxazines, thiazines, and azines are ortho-quinonoid derivatives. The future may show that this conservatism is well grounded.

The two closing sections of the book present a marked contrast. The penultimate chapter on anthraquinone and allied colours is, with two exceptions, already noted, detailed and comprehensive; the last chapter on indigoid colours is an unfinished fragment constituting a sad reminder of the sudden and premature close of an active life devoted to the theory and practice of colour chemistry.

To the student of organic chemistry this work offers a concise introduction to the fascinating though complex subject of synthetic dyes. To the expert colour-maker or user it supplies a full bibliography with copious references and an adequate index. Both classes of readers will find the book to be an excellent supplement to the author's earlier volume on the manufacture of intermediates. G. T. M.

Rea's "British Basidiomycetæ."

British Basidiomycetæ: A Handbook to the larger British Fungi. By Carleton Rea. (Published under the auspices of the British Mycological Society.) Pp. xii+799. (Cambridge: At the University Press, 1922.) 30*s.* net.

EVERY mycologist will welcome the appearance of this volume, which is issued under the auspices of the British Mycological Society and represents thirty years of careful and continuous field-work on the part of its author. The author, whose skill in distinguishing our fleshy agarics one from another has been freely placed at the disposal of so many students of fungi in this country, is to be congratulated heartily upon having crowned his life's labours with the publication of a work at once so comprehensive and so valuable for reference.

Massee's "British Fungus-Flora" appeared in the years 1892–1895. In the interval some hundreds of Basidiomycetæ, either new or new to Britain, have been discovered in this country—many of them by Mr. Rea himself—and descriptions of all these species are included in the present volume. In accuracy of description the book is an immense advance on anything previously produced in Britain.

There are a number of commendable features in the work: (1) Every species is numbered, Rea's last number being 2546; (2) the species actually seen are indicated by the letters *v.v.* (*vidi vivum*); (3) in the description of species the essential characters are placed in italics; and (4) the derivation and meaning of the name of each genus and species is given, philology thus illuminating mycology.

The classification adopted is based chiefly on the well-considered system set forth by Patouillard in his

"Essai taxonomique" (1900), and it therefore differs in many important features from that of Massee, which was based on the work of Fries. It is new to British mycologists, and will doubtless puzzle somewhat many of the older workers; but it represents an important attempt to incorporate in a systematic treatise the anatomical and microscopical data which various investigators have brought to light during the last half-century.

In the classification adopted by Fries, Berkeley, Massee, and others, the main divisions of the Agaricineæ were based on spore-colour. We were thus at the outset provided with Leucosporæ, Rhodosporæ, Ochrosporæ, Porphyosporæ, and Melanosporæ; but in the present volume these groups have disappeared and spore-colour has become a character of relatively minor importance. In Rea's classification, the Agaricales are divided into (1) the Agaricineæ, containing the bulk of the lamellate fungi in one sub-order Agaricaceæ; (2) the Cantharellineæ; and (3) the Boletineæ, the last named including Paxillus and Boletus. The divisions of the Agaricaceæ are based first on the nature of the receptacle, then on the presence or absence of a ring, etc.; and it is only the final distinctions, separating the genera from one another, which for the most part are based on spore-colour. No doubt this new classification has its advantages; but some of its defects are sufficiently obvious. Thus, while Anellaria differs from Panæolus in little more than the possession of a membranous, often fugacious, ring, we find that Anellaria is placed close to Lepiota and Panæolus close to Collybia. For Fries, the genus Panæolus included the species subsequently placed by Karsten in Anellaria. The reviewer cannot but feel with Fries that the species of Panæolus and Anellaria are closely related to one another and that these genera should not be so widely separated.

The writer is inclined to doubt whether spore-colour is only of such minor importance as is now supposed. There is every reason to believe that the genus Coprinus, with its parallel- or subparallel-sided gills and the ripening and discharge of its spores from below upwards on each gill, followed by autodigestion of the gills from below upwards, is monophyletic. Now the spores in this genus are all black or blackish fuscous. In it there are no species with white spores or spores that are pink, purple, ochraceous, or ferruginous. Yet in the genus there are species with rings, *e.g. Coprinus comatus*, and without rings, *e.g. C. picaceus*; species with fairly thick flesh, *e.g. C. atramentarius*, and species with membranous flesh, *e.g. C. plicatilis*; species with dimorphic basidia and species with quadrimorphic basidia; species with large and numerous cystidia and species without cystidia; species which live exclusively on dung and species which live exclusively on wood, etc.; yet, while the genus Coprinus was evolving, the colour of its spores remained constant. It is evident that, in the genus Coprinus, spore-colour is a more fundamental character than ring-formation. If this is so with Coprinus, it may well be the same with other genera of Agaricineæ. Rea's system of classification, although in some of its details it does not satisfy the writer, has the advantage that it will stir up thought and thus make for further progress.

"British Basidiomycetæ" is distinctly Mr. Rea's own book; and, in writing it, he has adopted as regards species a somewhat conservative and independent attitude. Thus he includes descriptions of certain species which are now known to be identical with others —*e.g. Coprinus oblectus*, which is undoubtedly identical with *C. sterquilinus*, and *Coprinus radians*, which is generally considered as identical with *C. domesticus*. His independence is further shown by the fact that in certain groups he has adopted his own views rather than those of his fellow-workers in this country. Thus, in treating of the Clavariæ, he has not followed entirely the revision of the British Clavariæ as given by Cotton; while, in some instances, in treating of the Thelephoreæ, he has accepted American views rather than those of Miss Wakefield.

The volume is indispensable to all students of fungi on both sides of the Atlantic; for it is only by a clear understanding of the first-described European species that New World plants can be correctly named. The task of describing two thousand five hundred Basidiomycetæ is no mean one; and botanists generally, as well as mycologists, are under a deep debt of gratitude to Rea, not merely for having accomplished it, but for having accomplished it so well.

A. H. REGINALD BULLER.

An Index to Periodical Literature.

(1) *The Subject Index to Periodicals.* Issued by the Library Association. K: Science and Technology. Pp. 555. (London: Library Association, Stapley House, 1922.) 35*s.* net.

(2) *The Subject Index to Periodicals, 1920.* Issued by the Library Association. A: Theology and Philosophy (including Folk-Lore). Pp. 98. (London: Library Association, Stapley House, 1922.) 6*s.* net.

WE congratulate the Library Association on this welcome addition (1) to the valuable subject indexes to periodicals which it has already published. The present index contains the titles of 15,000 papers, published during the years 1917–19, obtained from the examination of 400 periodicals. It would appear that more than half the papers indexed are in the English language, having been published in the British Empire

or in the United States. The language next in evidence is French.

The period covered—the second half of the war and the following year—was not very fruitful in scientific research, except in regard to subjects bearing upon the great conflict, but it is clear, both from the number of entries and from the number of journals consulted, that the index does not claim to be a complete record of all scientific and technical papers published during that period, but that a selection has been made. It would add to the value of these publications if the editors could see their way to include a list of the periodicals indexed in each section of these indexes when it is published. The inclusion of the name of a journal in such a list would not, of course, mean that all the papers printed in that journal had been indexed, but the omission of any journal from the list would definitely warn the reader that no papers in that journal had been included, and thus leave him to look up that journal if he thought it likely to contain papers on the subject of his study. It would also save the reader who wished to make a more exhaustive study of any subject from referring to journals which had been already examined. This is the plan followed in the lists of journals at the end of each volume of the "International Catalogue of Scientific Literature." In the present case, a list of the titles of the 400 journals examined would probably take up no more than three or four pages.

The usefulness of these indexes depends entirely upon a wise choice of the headings under which the titles are grouped. It may be assumed that the Library Association is partly guided in its choice of headings by experience of the inquiries made by readers asking for books.

The various headings are not arranged in any systematic way, and are not even divided according to the several sciences, but they follow one another in alphabetical order. The difficulty of this plan is that, when using such an index, it is not always possible to guess what heading will be chosen for a particular subject. This difficulty is, to a great extent, overcome in these subject indexes of the Library Association by the addition of numerous cross-references. Thus, under the heading "Refrigeration" we find a cross-reference to "Cooling Gases" indexed under "C." We might, however, not be so fortunate had we begun by looking up the subject of cooling gases under the heading "Gas." No doubt, the majority of those who use these indexes find a simple alphabetical arrangement of subjects more easy to understand than any systematic plan, and for that reason its use is justified.

In the preparation of this Index special attention has been paid to applied science and technology. Among headings which have a large number of entries of titles of papers are aeronautics; alloys; artillery; automobiles; coal; electric apparatus, power, heating and lighting; electroplating; fish and fishing; gas and oil engines; glass; iron; metals; mines; petroleum; photography; ships and shipbuilding; soils; wireless signalling.

(2) We are glad to find that the Library Association is continuing the publication of these subject indexes in other departments. Thus it has just issued a subject index for theology and philosophy (including folk-lore), indexing the literature of these subjects published in 1920, and occupying about ninety-six pages. This index contains titles of papers on psychology and psycho-analysis, as well as on philosophy and religion, and will therefore be of use to students of these subjects.

Our Bookshelf.

(1) *Boiler Plant Testing: a Criticism of the Present Boiler Testing Codes and Suggestions for an Improved International Code.* By D. Brownlie. Pp. xi+168. (London: Chapman and Hall, Ltd., 1922.) 10*s.* 6*d.* net.

(2) *Steam Power Plant Auxiliaries and Accessories.* By Terrell Croft. Pp. xv+447. (New York and London: McGraw-Hill Book Co., Inc., 1922.) 15*s.* net.

(1) MR. BROWNLIE has done great service in recent years in directing attention to uneconomical methods of steam production, and he has backed his criticisms by copious results of tests. The present volume contains an appeal for more rational methods of boiler testing, and criticises several existing codes, including that of the Institution of Civil Engineers. "A general impression also, on reading through the 'Civils'' code, is that boiler plant testing is an extremely complicated and difficult operation, which involves a knowledge of chemistry and mathematics quite beyond the ordinary engineer, and can only be carried out by the University graduate." Mr. Brownlie shows that boiler testing must be regarded as a thoroughly practical proposition which is necessary for the strictly utilitarian purpose of saving money. His criticism is constructive in that he gives full directions for carrying out practical tests, and includes a typical set of report sheets, with figures showing the results. The book is a distinct contribution to the subject, and it is to be hoped will lead to an early discussion and revision of the present codes.

(2) Considerable attention has been given recently to the formerly neglected auxiliary appliances connected with steam production. Pumps, feed-water heaters, fuel-economisers, condensers, steam pipes and traps are now taken seriously by the majority of engineers, and this consideration has led to the reduction of wasted heat. The engineer will find a great deal of useful information in this volume, which is of the nature of a joint effort on the part of a number of concerns and individuals. The matter included is not only serviceable for the purposes of the design and

arrangement of auxiliaries, but also conveys much useful information regarding their working and maintenance in practice. The subject is treated very thoroughly, and contains much that could only be found otherwise by searching through periodicals and the transactions of engineering societies.

Heat. By W. J. R. Calvert. Pp. viii+336. (London: Edward Arnold and Co., 1922.) 6*s*.

IT is sometimes difficult to justify the publication of a new text-book on a branch of elementary science, but Mr. Calvert has been so successful in presenting the subject of heat in an attractive and yet scientific manner that his book deserves a special word of commendation. The first part is intended to cover the ground of a general school education, and the second part brings the work up to University scholarship standard. The author realises that the majority of those who begin the subject will have little or no interest in experimental determinations unless it is made clear to them, at the outset, that objectives which appear to them reasonable cannot be reached without dealing with such measurements. He quotes with approval an appropriate sentence from one of J. B. Biot's works—"Toutes ces choses ne peuvent se déterminer sûrement que par des mesures précises que nous chercherons plus tard; mais auparavant il fallait au moins sentir le besoin de les chercher."

While practical applications have been emphasised, attention has been kept fixed upon the underlying principles. In all the experimental work the degree of accuracy likely to be attained has been carefully considered. In this connexion mention may be made of the details and dimensions which have been given in the case of many experiments of the laboratory or lecture type. We think the author is to be congratulated on having had the courage, even in so elementary a book, to give references to original papers. The few readers who look them up will gain a great deal, and even those who do not will at least be able to use the dates to get some idea of the chronological development of the subject. The book is the work of a teacher who has given much thought to the treatment of a familiar subject, and the result of his labours forms a valuable addition to the elementary literature of an important branch of physics.

(1) *Guide to the University Botanic Garden, Cambridge.* By H. Gilbert-Carter. Pp. xvi+117+24 plates. (Cambridge: At the University Press, 1922.) 3*s*. 6*d*. net.

(2) *An Alpine A B C and List of Easy Rock Plants.* Arranged by A. Methuen. Pp. x+35. (London: Methuen and Co. Ltd., 1922.) 1*s*. 6*d*. net.

(1) IN this attractive little handbook is a systematically arranged account of a number of the more interesting flowering plants which are cultivated in the University of Cambridge Botanic Garden, which should be of service to students in the Botany School of the University. The sequence is the familiar modern German one, and under each family is a short description of some of the genera and species which are regarded as specially worthy of mention. The plates, which are good full-page photographic reproductions, add to the value and attractiveness of the book. A clear plan of the garden indicating the larger plants with page-references to the trees, and an index of the genera and species mentioned in the book, enables the student to make full use of it. In deference to the oriental scholars who have loved and befriended the garden, the author has included the eastern names of some of the plants, with quotations illustrating the use of these names. A historical note gives the date of the foundation of the Cambridge Garden as 1762, and in 1831 the removal to the present site was authorised.

(2) Mr. Methuen's notes are for the beginner and the amateur. Their purpose is to give a list of the most attractive and the most easily grown Alpine flowers and to guide in their placing and cultivation. A few general rules are given for making a rock garden and planting and tending Alpines. The greater part of the book is an alphabetical list of the species recommended, with indication of the colour of the flower and very brief notes on cultivation. The book is the outcome of the compiler's own experience and conveys a good deal of useful information in a very small space.

The Origin and Development of the Nervous System: from a Physiological Viewpoint. By Prof. C. M. Child. (The University of Chicago Science Series.) Pp. xvii+296. (Chicago: The University of Chicago Press; London: The Cambridge University Press, 1921.) Price 1.75 dollars net.

IN the preface to his book, Prof. Manning Child points out that, considered from a physiological viewpoint, the origin of the nervous system must be sought in conditions present before the appearance of a morphological nervous structure. In accordance with this, the earlier chapters are devoted to a discussion of the origin and nature of the pattern which constitutes the organism as a whole, and to a consideration of the experimental investigation of some of the physiological conditions which antedate the appearance of the nervous system. A brief summary is given of the evidence for the existence of physiological axial gradients—*i.e.* graded differences in the organism in the rate of the fundamental activities of protoplasm and in the conditions associated with these activities—as the essential factors in the organismic pattern. An attempt is made to show that the nervous system is the physiological and morphological expression of the excitation-transmission relations, first with respect to the primary physiological gradients, and later with respect to the progressive developmental complications as they arise.

Prof. Child admits that with many of his points only suggestion, inference, or weighing of probability is at present possible. For this reason, and on account of the necessary technical detail, the book is more suitable for the biologist and physiologist than, as suggested in the note on the University of Chicago Science Series, to which this volume belongs, for the educated layman.

The Life of the Weevil. By J. Henri Fabre. Translated by Alexander Teixeira de Mattos. Pp. viii+278. (London: Hodder and Stoughton, Ltd., 1922.) 8*s*. 6*d*. net.

GATHERED together in this volume are the various essays on weevils contained in the "Souvenirs entomologiques" of Fabre. Chapters i. and vi.-ix. have already appeared wholly or in part in a previous translation, as have also chapter v. and parts of chapters vi.

and xii. They are, however, retranslated by permission of the publishers for the purpose of the present collected edition of English translations of Fabre's entomological writings. There is no doubt that the rendering of the latter into English will do something towards arousing interest in the phenomena of insect behaviour. We may even be permitted to express the pious hope that it will tempt the collector to turn aside from the mere acquisition of specimens and to observe the living more than the dead insect. The great family of the Curculionidæ, with more than 20,000 described species of weevils, provides a rich store of material for observation. Some of the most interesting features in the life-habits of these insects are discussed in the pages before us. Although lacking in the dramatic incidents so inseparably associated with the Hymenoptera, the behaviour of weevils as told of Fabre, and reproduced in this translation, will provide entertainment both to the general reader and the entomologist. A. D. I.

Modern Microscopy: a Handbook for Beginners and Students. By M. I. Cross and Martin J. Cole. Fifth edition, revised and rearranged by Herbert F. Angus. Pp. x+315. (London: Baillière, Tindall and Cox, 1922.) 10*s.* 6*d.* net.

THAT there has been a call for a fifth edition of this book we can well understand, as it gives an excellent introduction to all branches of microscopy. In the opening chapters the mechanics and optics of the microscope are described, and instructions are given on the general method of using the instrument, illumination, drawing and measuring apparatus, and for tests of the optical system.

In the second portion of the book, chapters written by specialists in their respective subjects deal with various aspects of microscopy. Thus, Mr. Barnard and Drs. Cooke and Drew describe the use of the microscope in medicine, including dark ground illumination; histology is dealt with by Mr. Cole, including hardening and embedding tissues and section cutting; and Prof. Cheshire writes on the microscope in geology and discusses simply and clearly the polarisation of light. Another interesting chapter is that by Mr. Cutler on the microscope in agriculture, particularly the protozoa of the soil. Pond life, foraminifera, mycetozoa, mosses and liverworts are some of the other subjects dealt with, and a final chapter by Mr. Cole describes the preparation and mounting of common objects. A useful glossary of technical terms is included, together with details of the Royal Microscopical Society's standards, the specifications of the British Science Guild, and microscopical societies and clubs. The book is very readable and well illustrated, and the information contained in it is accurate and up-to-date.

The Wirral Peninsula: an Outline Regional Survey. By W. Hewitt. Pp. x+293. (Liverpool: University Press of Liverpool, Ltd.; London: Hodder and Stoughton, Ltd., 1922.) 7*s.* 6*d.* net.

MR. HEWITT has selected a small and well-defined area, and in successive chapters has considered its physical, biological, and human aspects, in an endeavour to explain the geographical evolution of the area. The social and economic conditions of any region must necessarily depend to a large extent on its position, natural features, soil, climate, and vegetation. Wirral is only some 130 square miles in extent and until the middle of the nineteenth century was almost entirely agricultural. But the rapid increase of manufacturing industries across the Mersey and growing commercial importance of the Mersey estuary have resulted in an industrial invasion of the left bank of the river. Industries promise to show a steady increase in importance. Agriculture will probably retain its hold, but considerable changes in methods and conditions are taking place. The social evolution which Wirral is now undergoing can be adequately understood only by a study of its regional geography in the light of the past.

The volume is an example of the growing attention that is being paid to regional survey, and is a welcome addition to the small number of studies of this kind which have been prepared in this country. We gather that the author regards it as a preliminary sketch, and that a fuller survey is in course of preparation.

An Experiment in Synthetic Education. By Emily C. Wilson. With Chart for Five Years' Work. Pp. 62. (London: George Allen and Unwin, Ltd., 1921.) 4*s.* 6*d.* net.

MORE than one hundred years ago, Herbart sketched out his ideal system of education, which was to utilise all knowledge for the formation of character. For this purpose the knowledge was to be presented as a unity instead of in the usual way which drew a hard and fast line between each subject. Since his day the specialisation of knowledge has increased so much that the problem, difficult though it was then, is infinitely more difficult now; the intelligent teacher who would put his children into touch with all aspects of modern knowledge, while yet giving the requisite historical background for the understanding of that knowledge, is faced with difficulties at every stage.

This little book shows how one school attempted to deal with the problem. Each subject for convenience demands a name standing for particular aspects of knowledge, but it should be treated in relation to the other subjects. A chart giving details of a five years' scheme is appended. It is an interesting and suggestive experiment.

Leçons sur les Invariants Intégraux: Cours professé à la Faculté des Sciences de Paris. Par Prof. E. Cartan. Pp. x+210. (Paris: A. Hermann et Fils, 1922.) 20 francs.

AN account of Poincaré's theory of integral invariants with special reference to analytical dynamics is given in the volume under notice. It opens with Hamilton's principle of least action and contains detailed discussions of such questions as differential systems admitting infinitesimal transformations. There are also chapters on the application of Poincaré's theory to the problem of n bodies and to Fermat's principle in optics. Much matter collected here can only be found scattered elsewhere in scientific journals.

Rayonnement et gravitation. Par Félix Michaud. Pp. viii+62. (Paris: Gauthier-Villars et Cie, 1922.) 6 francs.

AN attempt which does not go into details to trace all physical phenomena back to radiation, gravitation for example being ascribed to ultra X-rays.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

On the Element of Atomic Number 72.

DANS le numéro du 20 janvier 1923 de NATURE, MM. Coster et Hevesy annoncent qu'ils ont obtenu le spectre de haute fréquence de l'élément de nombre atomique 72.

Ce résultat très important marque un progrès dans la question que nous avons ouverte (A. Dauvillier, *Comptes rendus*, t. 174, p. 1347, mai 1922 ; G. Urbain, *Comptes rendus*, t. 174, p. 1349) ; il est seulement regrettable que MM. Coster et Hevesy se soient efforcé de jeter le discrédit sur nos propres résultats.

Il nous paraît d'abord nécessaire de préciser les faits :

Deux raies [1] de haute fréquence caractéristiques de l'élément 72 ont été observées avec les oxydes provenant des queues de fractionnement des nitrates du groupe ytterbique, c'est-à-dire dans les mêmes oxydes où l'un de nous, il y a douze ans (G. Urbain, *Comptes rendus*, t. 152, p. 141, 1911) avait observé des raies d'arc qui, n'étant attribuables à aucun élément connu, ont été considérées comme appartenant à un élément nouveau, le Celtium.

De leur côté, MM. Coster et Hevesy ont observé dans des produits zirconifères d'origine norwégienne six raies de haute fréquence caractéristiques de l'élément 72.

Ce résultat a été immédiatement contrôlé par l'un de nous avec un échantillon de zircone. Les raies attribuables à l'élément 72 coïncident exactement [2] avec celles observées avec les terres ytterbiques, avec cette seule différence que la proportion de l'élément 72 y est notablement plus grande.

Nous concluons de ces faits que MM. Coster et Hevesy sont mal fondés à revendiquer la découverte de l'élément 72 alors que nos publications sont de 8 mois antérieures à la leur, et qu'il s'agit bien du même élément.

Les clichés que nous possédons n'ont pu être reproduits et publiés à cause de la faiblesse des raies, mais nous les tenons à la disposition de MM. Coster et Hevesy qui pourront les examiner de concert avec nous au laboratoire de M. de Broglie où ils ont été obtenus.

Eu égard aux considérations théoriques qui forment la base de l'argumentation de MM. Coster et Hevesy il nous suffira de dire :

1°. Dans sa première note de 1911, Urbain a pensé pouvoir s'appuyer sur des variations de propriétés magnétiques et chimiques pour attribuer au celtium des propriétés intermédiaires de celles du lutécium et du scandium. Les faits observés depuis imposent de faire des réserves sur cette question d'interprétation, d'ailleurs secondaire au point de vue qui nous occupe.

2°. L'examen du spectre de haute fréquence dans les produits celtifères a précisément eu pour but de rechercher si cet élément pouvait être identifié à l'élément 72. Il eût été dès lors singulier après avoir observé ce spectre de haute fréquence de ne pas l'attribuer au celtium. Mais quand bien même le spectre d'arc et le spectre de haute fréquence en question ne seraient pas attribuables au même élément, comme nous l'avons logiquement admis, il n'en resterait pas moins vrai que nous avons découvert les premiers l'élément 72. En conséquence MM. Coster et Hevesy n'avaient pas le droit de lui donner un nom nouveau.

3°. MM. Coster et Hevesy attribuent à l'élément 72 la valence 4, ce à quoi nous n'avons à faire aucune objection. La question est de savoir si un élément tétravalent peut accompagner les terres rares de manière à se retrouver dans les dernières eaux-mères des fractionnements. Or le cas se présente constamment pour le cérium, à la fois trivalent et tétravalent. Il y a même, entre ces deux états du cérium, un constant équilibre. Le cas se présente encore pour le thorium qui, dans les minerais, accompagne toujours les terres rares trivalentes et dont on retrouve toujours des traces, après traitements, à la queue des fractionnements qui classent les terres rares dans l'ordre de leur solubilité.

De même on retrouve constamment le germanium avec l'arsenic ou le molybdène, l'indium avec le zinc, etc.

On ne saurait donc affirmer, comme l'ont fait MM. Coster et Hevesy, que l'élément 72 ne peut se retrouver dans les dernières eaux-mères des fractionnements des termes ultimes de la série des terres rares si ce n'est pour en conclure que nous n'avons pu observer son spectre là où cet élément ne pouvait se trouver. Un tel raisonnement est évidemment sans valeur et ne présente d'autre intérêt que d'être tendancieux.

G. URBAIN.
A. DAUVILLIER.

Paris, le 27 janvier.

[1] Les autres raies de cet élément coïncident avec des raies du lutécium et du néoytterbium.

[2] Un cliché effectué avec un autre fractionnement de terres ytterbiques, en améliorant les conditions expérimentales (oxydes fortement comprimés et calcinés dans le vide, foyer anticathodique linéaire, etc.), nous avait déjà fourni des lignes plus nettes et plus intenses, mesurables avec plus de précision. Nous trouvions ainsi : $\beta_2 = 1322{\cdot}8$ et $\alpha_1 = 1564{\cdot}1$ U.X., chiffres coïncidant avec les valeurs interpolées. La recherche du zirconium, effectuée par le spectre d'arc et le spectre de haute fréquence, a donné un résultat négatif.

Meteorological Nomenclature and Physical Measurements.

WITH concern, not unmixed with amusement, I have read in the issue of NATURE for January 27 the desponding reports about the "Position of the Scientific Worker" on p. 132, and Dr. Mill's playful banter about "Progressive Meteorology" on pp. 107-109. The uninitiated can scarcely fail to regard the latter as deriding some recent meteorological work as regards the choice of appropriate names and units of measurement for the physical quantities involved ; while I have good reason for regarding it as a serious effort to make plain some rough places in the path of future students of meteorology.

By way of illustrating the importance of units let me say that this week-end, by the accident of having to revive past memories of the physics of the atmosphere at a lecture in the University of Birmingham, I have happened upon two generalisations, new to me and perhaps also to other readers of NATURE, which Dr. Mill may regard as important for the comprehension of the general problem. One is that at the level of eight kilometres (all over the world, so far as our limited knowledge extends) normal isobars are also normal isotherms and the temperature is everywhere numerically two-thirds of the pressure. The other is that the range of temperature during the year at a selected locality of the earth's surface, possibly at any locality, is the saturation-adiabatic projection upon the surface of the range of temperature at any level above ground. The language is horrifying in its technicality ; but if the two propositions are true,

even for comparatively restricted areas, they present a view of the normal state of the atmosphere which is worth remembering. With the terminology and units which I have employed they are easy to remember. If Dr. Mill will translate them into the vernacular which he favours he will find the statements much more difficult to word.

As to terminology, can any one estimate the debt which meteorology owes and will continue to owe to Bjerknes for the happy inspiration of the name "polar front"? What its real meaning is we have not yet found out; but it is a banner under which knowledge is enlarged. Or can any one say how the fate of Scott's Antarctic expeditions would have been affected if the meaning of "katabatic" had been understood in 1900. The development of the science of meteorology is a strenuous task. I do not suppose that Dr. Mill intended his criticism to be as destructive as uninitiated readers will think it to be. Somehow the picture which his review calls to mind is that of the three jovial huntsmen: "We'en powlert up and down a bit and had a rattling day." There are occasions when there are obvious discontinuities in psychology. Once upon a time, years ago, as college tutor in Cambridge I went down to see the boat-races. Being late, I found the leading boats of the first race already past the winning post, among them one of my own college which I had gone down to cheer. It was a perfect summer's day, and I found the crew in lonely solitude, lolling about in the boat after their labours, in all the attitudes of summer idleness. I went up to them and by way of being cheerful remarked, "You seem to be having a picnic." To my astonishment no one spoke; and presently the man nearest to me grunted, "It's been grim earnest here, Sir." They had been chased all over the course and were too exhausted to stand and too despondent to speak.

I am not yet come to that pass; but I feel in like manner that Dr. Mill in his dignified position has not really appreciated what the stress of meteorological work means. It is only too true that our craft rows its course in continual danger of being bumped by a crew that bases action upon its ignorance of the subject and not upon its knowledge. That is precisely the situation which the National Union of Scientific Workers finds so depressing, and to me, with a full experience of every phase of success and failure in boat-racing, the cheers from the bank to the boat that is pressing us are a reminder that science in this country might be encouraged rather than depressed if the members of its own household would visualise the situation a little more deftly.

I have never supposed that new units and new terminology can be anything but distasteful to the veteran, even to myself. I am not so self-confident as to assume that the ultimate solution will be found in the way that seems to me the most direct. All I ask is that those who criticise should face the problem with a policy. I find it difficult to regard the ordinary British attitude as indicating a policy: it is our income-tax which goes to teach every child in the country the metric system, and every child who learns science is taught at our expense to use the metric system and to "chuck it" as soon as he leaves school. If that is really an educational policy I can find no polite adjective in the dictionary which will describe it. NAPIER SHAW.

January 30.

The Identity of Geber.

I AM glad to see that Mr. Holmyard (NATURE, vol. 110, p. 573) has also been led to doubt the validity of much of the criticism of the authenticity of the Latin works attributed to Geber. In the recent work of Prof. A. O. von Lippmann "Die Entstehung und Ausbreitung der Alchemie," the destruction of the Latin authorities has passed all bounds of restraint. A treatise which refers to Geber, or gives doctrines resembling his, which could possibly have been written before 1300, the date of the earliest Geber MS., is *pseudographisch, untergeschoben*, or the work of *Fälscher*. Important treatises are dismissed in footnotes without discussion as spurious. Geber's fall is bringing down many other authors. In some fairly early authorities there are references to *a* Geber, but in quoting these in other parts of his book, von Lippmann has left out the text containing the name of Geber. In other places, in his quotations, the omission of "et" (=and) is marked by a row of dots, and in giving the *content* of the opinions of other writers, Lippmann's book becomes quite untrustworthy when it reaches the Latin authors.

The discovery of the original MSS. is the final test. Boerhaave ("Elementa chemiæ," 1732, i. p. 15) says that the Arabic works of Geber were translated by Golius, who was professor of oriental languages at Leyden; in Shaw's translation of Boerhaave's book (1741, i. p. 26, note 3) it is stated that Golius presented the MS. of Geber to the Leyden library, translated it into Latin, and published it in the same city, first in folio and afterwards in quarto, under the title "Lapis Philosophorum." In the catalogue of Golius's library I find that there is mention of an Arabic MS. bearing the name of Geber and treating of alchemy, but the few MSS. examined by Berthelot, including MSS. from Leyden, were quite different from the works in Latin. The Leyden MS. may have been lost (as some of the Greek ones at Paris have been).

In the Latin Geber there are long arguments refuting those who deny the possibility of the Great Work. Berthelot says that an Arabic writer of the previously assumed period of Geber (*c.* 750–800 A.D.) would have had no doubts as to this possibility. This is incorrect. Prof. Wiedemann, whose services in this branch of historical research have been extremely valuable, has published MSS. of this period, in which it is said that the failure of alchemists to carry out their work of transmutation had become "proverbial" (Abu Jusuf, d. 798; Aldschaziz, d. 869, who said there was no alchemy; Alkindi, d. 873, who said all alchemists were liars). This argument, therefore, falls to the ground.

The logical arguments are, said Berthelot, reminiscent of the Schoolmen of a later period (say 1200–1250, in which he puts the Latin author). He does not say what these arguments are, but those I have met with are taken largely from Aristotle, whose works were translated into oriental languages at an early period.

Geber, according to Berthelot, showed an advanced rationalism in contesting the influence of the planets, which was accepted by the Arabic Jâbir, whose works are extant in Arabic, but are different from Geber's. A belief in astrology cannot be used to date any historical period, and apart from this, the Latin Geber explicitly admits the influence of the stars, but says "The work will be duly performed by Nature *under a due site* convenient for it, without any previous considerations of it."

"The ideas and facts developed in the writings of the pseudo-Geber," said Berthelot, "are frequently expressed in the same terms in the authentic works of Roger Bacon." I do not wish to enter into a discussion of the authenticity of these particular works of Bacon; it is only necessary to remark that in the one to which Berthelot's remarks seem to

apply the name of Geber is cited, through Avicenna's "De Anima" (the phrase is given by Hoefer, i. 329, as Bacon's), which work is, naturally, condemned by Lippmann, on quite inadequate grounds, as "pseudographisch." That it differs in style from the "Canon" is probably correct, but Newton's "Daniel and the Apocalypse" differs in style from the "Principia." Avicenna's "De Anima" was condemned as spurious by Dr. James in his "Medical Dictionary" (London, 1743, vol. i., unpaged). The quotation in Avicenna is not to be found in the Latin works of Geber.

According to Berthelot the "Liber Septuaginta" (the Latin MS. of which was noted by Hoefer, whose valuable pioneer work has been considerably underestimated) is entirely different in style and content from the Latin Geber, although he attributes it, on what seem insufficient grounds, to Jâbir. There are some strikingly similar passages in the above work and in the Latin Geber, though I do not assert that they had the same author.

For some years I have asserted in my lectures that the criticisms of Berthelot were unsatisfactory. There are many other reasons why the arguments of Berthelot should be rejected and a new start made. Mr. Holmyard inclines to the original view that the Arabic Jâbir and the Latin Geber are one; my own view, which like his is still hypothetical, is that a Greek, Syriac, or Hebrew MS. may be as likely to be the *original* source as an Arabic one. The details of the life of Geber are very contradictory, but he is said to have been "a Christian who afterwards became a Mohammedan," or "of Tarsus." This is suggestive.

The "Summa perfectionis" is probably the earliest Latin work of the group attributed to Geber. It differs only little from the Greek writings of Alexandrine authors in its ideas, and the doctrines it teaches do not seem to represent that remarkable advance which is held to throw doubt on its early date. The "Testamentum" referred to by Mr. Holmyard differs in content and outlook from the "Summa"; it does not appear in the earliest printed edition of Geber's works (British Museum, catalogued as possibly printed at Venice in 1475, but I am informed by the authorities in the Incunabula Department it was probably printed at Rome not before 1480–1490). The "Testamentum" first appeared in the Vatican edition (? 1525; the 1480 was also a Vatican edition; Kopp, Hoefer, and Berthelot have been confused by editions of Geber which they have not seen). The "Liber de investigatione" may be a compilation by some later writer. The "Alchimia Geberi," of which Kopp, Hoefer, and Berthelot speak, is not a separate work, but merely an edition of Geber's works. As Mr. Holmyard seems to have gone some distance in another direction, I thought it useful to state briefly what conclusions I have reached; the detailed justification of these would take up far too much space. The "pseudographic" school, however, do not seem to have made out their case.

The Stoat's Winter Pelage.

A FRIENDLY stoat, which has made our flower-garden and rockery his hunting-ground for mice and voles during the last three years, has donned his winter livery of ermine, and become very conspicuous—a snow-white little athlete—amid the greenery of the present exceedingly green winter.

This seasonal change of the stoat's brown summer pelage to creamy white is regulated, not by winter temperature, but by latitude. Invariable in the stoats of the Scottish Highlands, nearly so in those of the Scottish Lowlands, it becomes gradually less frequent towards the English Midlands; until in the southern counties a complete change of hue is exceedingly rare. This change is not due to the growth of a new coat; it is the old fur that becomes white. Nor is prevailing temperature the cause of change. Here, on the western Scottish seaboard, winter is usually very mild; snow seldom falls and still more seldom lies. *Clianthus puniceus*, from the north island of New Zealand, and *Abutilon megapotamicum*, from Brazil, have been flowering profusely on walls in the open all through this winter; yet our stoats regularly assume the protective winter garb of circum-polar animals; while in Warwickshire and Leicestershire, where the average winter temperature is far more severe, a complete change in the stoat's pelage very rarely occurs.

May we not recognise in this a heritage from the last ice age? So long as the land so far south as Herts lay under the ice, stoats in the Thames valley and south thereof must have worn the ermine pelage—at least in winter, and so did those which followed the ice in its northward retreat. But some thousands of temperate seasons have enabled the race of stoats that remained in the southern counties to dispense gradually with a costume which has become the very reverse of a protective disguise.

A few thousand years more and it may be as difficult to find a white ermine in Caithness as it is now in Cornwall!

Stirling's Theorem.

FOR very large values of n, Stirling's theorem,

$$i.e.\ \text{Lim}\ \frac{\lfloor n}{n^n \epsilon^{-n} \sqrt{n}} = \sqrt{2\pi},$$

reduces in its logarithmic form to

$$n \log n - n = \log \lfloor n.$$

It is in this form that the formula is required in Planck's radiation theory. Wanting to use this formula, and unwilling to make my students go through the proof of Stirling's theorem as given, for example, in Chrystal's "Algebra," I thought of the following deduction, and should like to know if it is sound or if it has been given before.

When $dn = 1$

$$\log n = \frac{d}{dn} \log \lfloor n,$$

and since n is to be very large the value of dn is an infinitesimal. Therefore we may say

$$\log n\, dn = d \log \lfloor n$$
$$\therefore \int \log n\, dn = \int d\,(\log \lfloor n)$$
$$\therefore n \log n - n = \log \lfloor n,$$

which is the form required.

Stonehenge: Concerning the Four Stations.

JUST within the surrounding earthwork of Stonehenge there are two stones symmetrically placed with reference to each other on opposite sides of the centre. There are also two low earth heaps or mounds in corresponding complementary or reversed

positions. A general description of these "Four Stations" was given by me in NATURE for April 1, 1922 (vol. 109, p. 410), with a plan (reproduced herewith, Fig. 1) drawn to scale and photographs of the stones.

The two so-called mounds are of very slight elevation, and are scarcely noticeable on the ground: each has a sort of hollow or crater in its centre. By Petrie's system the two stones are numbered 91 and 93, and the corresponding pair of mounds Nos. 92 and 94.

In the hollow of mound No. 94 Colt Hoare reports that he found "a simple interment of burned bones" ("Ancient Wilts," i. p. 145). On the strength of this discovery it has been assumed that the two mounds are Round Barrows, and (based on this assumption) it is inferred that Stonehenge was constructed probably near the end of the Bronze Age or perhaps even later.

The advocates of a Bronze Age date for Stonehenge specially rely upon this as conclusive evidence in support of their theory. Dr. Rice Holmes, for example, makes the somewhat positive assertion as follows:

> "The stones [of Stonehenge] were certainly not standing when Round Barrows were first erected on Salisbury Plain; for one is contained within the *vallum*, which, moreover, encroaches on another" ("Ancient Britain," p. 476).

In my letter in NATURE (April 1, 1922), I gave evidence for the opinion that these two earth heaps are not the remains of barrows, but are the sites of a pair of stones that had been removed. These stones, when in position, corresponded exactly with the pair of stones which still remain in place.

In the *Antiquaries Journal* for October 1922 (p. 344, footnote), Dr. Rice Holmes, in reference to this matter,[1] remarks:

> "Round barrows were erected towards the end of the Neolithic Age in Scotland, Yorkshire, and Derbyshire; but Mr. Stone is, I believe, the first to suggest that a round barrow of that period exists at Stonehenge."

But I made no such suggestion—in fact, the special purpose of my communication was to show that the so-called mounds were *not* barrows. Perhaps Dr. Rice Holmes will re-read my letter in NATURE of April 1 last.

The fact that "a simple interment of burned bones" was found by Colt Hoare in the hollow of site No. 94 is, of course, no evidence that the place was a barrow. Similar casual interments of burned bones were also found deposited in the adjacent "Aubrey Holes," which obviously were not the sites of barrows.

DITCH
No. 92 MOUND
No. 91 STONE
The two stones and the two mounds are symmetrically placed with reference to each other and to the main axis of the structure. Their centres are moreover all on the same radius, and their centre lines make an angle with each other of 45 degrees.

FIG. 1.—Plan of Stonehenge. Scale—120 feet to 1 inch.

That these mounds are really positions which were once occupied by stones has, however, now been placed beyond doubt by the excavations lately carried out by Col. Hawley, in the course of which the crater or hollow in the middle of one of these sites (No. 92) was completely cleared down to the original chalk rock. I inspected the bottom of the hole when it had just been cleared out, and it was evident that it had been dug as the foundation pit for a large stone. There was no indication of any barrow having ever existed on the site.

In his report published in the *Antiquaries Journal* for January 1923 (pp. 15-16), Col. Hawley, in reference to this, remarks:

> "Nearly in the middle of the place [No. 92] was a large hole. Sir Richard Colt Hoare mentions having opened it without result, consequently it was in a very disturbed state and afforded nothing of interest until it had been emptied. It was then seen that it must formerly have contained a large stone, perhaps about the size of the one [No. 91] lying near the rampart a little way to the east,

[1] Dr. Rice Holmes makes a mistake in his reference, which he gives as NATURE, April 29, 1922, p. 563.

and the bottom showed irregularities indicating the pressure upon it of an irregular base of a stone.

"On the north side, forming part of the hole, was an incline in the solid chalk for introducing the stone somewhat similar to those met with in the Stonehenge circle.

"The hole was about 4 feet deep."

It appears probable that most of the material of these so-called mounds is merely the spoil thrown out by Colt Hoare in making his excavations. Before Colt Hoare's time we find these two sites are always referred to as cavities or depressions (not as mounds), and we may infer that these cavities were the hollows left after the removal of the stones. The following extracts are quoted from well-known authorities:

William Stukeley, 1740.—"The two cavities in the circuit of our area, very probably were the places where two great stone vases were set" ("Stonehenge," p. 14).

John Wood, 1747. — "Two stone Pillars appear at the foot of the inner Bank next the Area in which the Building stands; and these are answered by two Spherical Pits at the foot of the same Bank" ("Choir Gaure," pp. 43-44).

Dr. John Smith, 1771. — "Directly north and south of the temple, just within the vallum of the ditch, is the appearance of two circular holes, encompassed with the earth that was thrown out of them. But they are now almost effaced by time" ("Choir Gaur," p. 52).

Waltire, 1792. — "There are two clayed pits, and two stones near the ditch" (Quoted in Britton's "Wilts," ii. p. 122.)

Rev. Richard Warner, 1801.—"Two other smaller stones are found on the inner bank of the surrounding ditch, exactly opposite to each other, in a direction east and west; as well as two circular depressions, about sixteen feet diameter, in the same bank, one lying S.S.E. and the other W.N.W." ("Excursions from Bath," p. 177).

We may conclude therefore:

(*a*) That the sites Nos. 92 and 94 were once occupied by stones corresponding with the now existing stones Nos. 91 and 93.

(*b*) That in the Bronze Age period the stone had already been removed from site No. 94, as a cremated interment was found by Colt Hoare in the foundation pit.

This latter conclusion (*b*) may prove of further interest in connexion with the history of Stonehenge. If supported by other evidence, it may be taken to indicate that in the Bronze Age the dilapidation of Stonehenge had already begun.

The Retreat, Devizes,
January 15.

A Double-Vertical-Reflection Mirage at Cape Wrath.

ON the morning of December 5, 1922, about 10.30 A.M. G.M.T., Mr. John Anderson, lightkeeper at the Cape Wrath Lighthouse, Durness, observed a mirage of an unusual character. Mr. Anderson focussed his telescope on a sheep which was grazing on top of a conical hill (height about 200 feet) about a quarter of a mile away, and immediately noticed an unusual appearance in the atmosphere around. On swinging the telescope slightly upward, he observed that a belt of the atmosphere appeared to be land and sea, giving a perfect representation of the whole of the coast line from Cape Wrath to Dunnet Head.

The appearance in the mirage was an exact replica of what would have been seen from a distance of about 10 miles out at sea. In a direction south

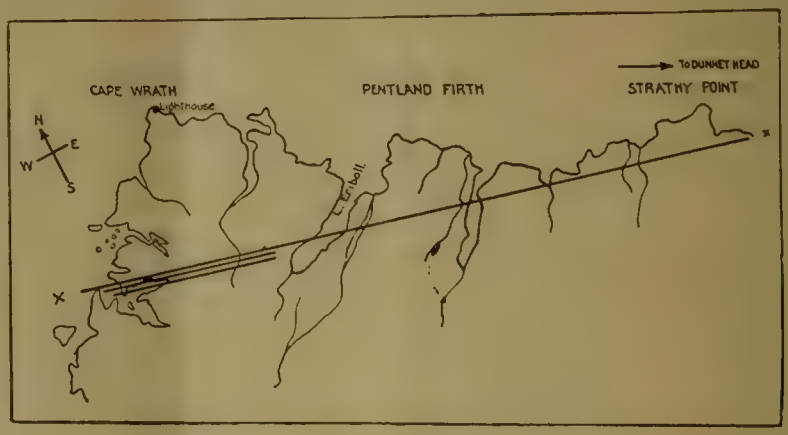

FIG. 1.

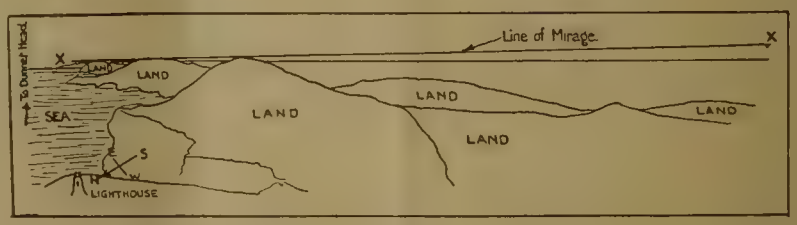

FIG. 2.

of the lighthouse there were three repetitions of the mirage one above the other, with sea separating each pair. The entrance to Loch Eriboll and the other bays could be seen and easily recognised in the main mirage, though Cape Wrath itself was rather indistinct.

The accompanying map (Fig. 1) shows the apparent position of the mirage and the outline of the coast, while the sketch (Fig. 2) gives a rough idea of how the country appeared to the observer. The mirage was hidden at one point by a hill.

The mirage was practically invisible to the naked eye, and was only visible from a very restricted area. Mr. Anderson states that it was not visible at a distance of 20 yards either way from his original position, but was still visible 4 or 5 yards from that point. Mr. Anderson estimates the apparent height of the image above the ground as about 1000 feet, in a southerly direction, while the distance from Cape Wrath of the triple image shown on the map is about 12 miles.

The phenomenon was observed for about thirty minutes, when it was blotted out by heavy, dark clouds from the south-west. Within a short time the sky was darkly overcast and rain began to fall, lightly at first, accompanied by slight fog; later rain fell very heavily, the raingauge giving a total of 1·97 inches for the afternoon.

The mirage was seen by practically all the residents at the station.

The meteorological conditions do not point to anything extraordinary. The synoptic chart for 7 A.M. shows an anticyclone centred westward of the mouth of the English Channel, with a very slight ridge of high pressure extending over Ireland and up the West Coast of Scotland. The temperatures at 7 A.M. were 48° at Wick and Stornoway, 51° at Castlebay, and 55° at Aberdeen. There was therefore a fairly sharp discontinuity of temperature along a line just south of Cape Wrath. The wind at 7 A.M. at Cape Wrath was from west by north. By 1 P.M. a secondary depression had advanced from the Atlantic, and was centred about 50 miles north of Stornoway, giving a south-westerly trend of isobars over the coast line from Cape Wrath to Dunnet Head. The temperature at Stornoway was now 52°, but only 47° at Wick, where the wind was still light.

The mirage was seen at 10.30 A.M., at the time when the wind was backing in front of the depression. The Deerness anemograph shows a slight backing of the wind from west by north at 10.30, and a further slight backing to west by south about 11 A.M. The wind blew steadily from west by south until 3.30 P.M., when it shifted to north in the rear of the secondary.

It will be noted that the phenomenon occurred at a time when the warmer current in front of the secondary depression had not completely displaced the colder air from the immediate vicinity of the coast line. There would remain a cold pocket of air under the cliffs, and other masses of cold air would probably be trapped by the hills near the coast.

The only suggestion which I can offer as a basis of explanation for the phenomenon is that there was a sharp surface of discontinuity—approximately vertical—between the warm air over the sea and the cold air under the cliffs, and that some distance inland there was another nearly vertical surface of discontinuity between the cold air near the coast and warm air which had penetrated inland through a gap in the hills south of Cape Wrath.

Reflection of light at two such surfaces of discontinuity would account for the phenomenon, the effect being that produced by two mirrors, one in front, and one behind, the observer. There should be a small amount of reflection at any sharp surface of discontinuity, perhaps sufficient to account for the phenomenon being visible through a telescope. The extremely small limit of the region from which the phenomenon was visible would place the inland discontinuity near to the observer. The effective surface of the mirror may have been quite small.

Mr. Anderson records that there was a slight fog when the rain came. The fog would be produced by the mixing of the warm humid current with the colder air which had previously remained over the coast.

The phenomenon has been called a mirage, but the mirage as ordinarily understood is either an effect of refraction in air stratified horizontally, or, in the case of inverted mirage, is an effect of reflection at a horizontal surface at which there is a rapid change of density. But the admitted theory of formation of inverted images confirms the claim that there should be reflection at a surface of discontinuity of density. The phenomenon described above might perhaps be named a "vertical-reflection mirage," to distinguish it from the ordinary mirage due to refraction or reflection in air stratified horizontally.

No other records of similar phenomena can be traced, probably on account of the fact that such mirages are never likely to be visible to the naked eye. The telescope is useful in such cases only in so far as it limits the amount of light reaching the observer's eye. A plain tube without lenses would probably have shown the mirage more clearly than a telescope.

Mr. Anderson has been keeping a watch for others, but so far without success. This particular observation has been perhaps due in part to a series of happy accidents, in that the observer happened to be in the best position to note the effect, at the time when a wandering sheep roused his curiosity. Much credit is due to him for the trouble he has taken to draw the map and sketch, and to write a very detailed account of what he saw.

D. BRUNT.

January 26.

The Sugar-Cane Mealy-Bug.

I HAVE just received a very interesting paper on the sugar-cane mealy-bug (*Pseudococcus sacchari* Ckll.) from Mr. W. J. Hall, of the Ministry of Agriculture, Egypt. He describes the insect as being so injurious that "the whole future of the industry hangs in the balance." When I was recently in Madeira I examined the sugar-canes wherever I went, and found only a sparing and local infestation by *P. sacchari*. I had no microscope with me, but the determination was confirmed by Mr. E. E. Green. The insects may be found on the canes near the cliffs below the new road, a short distance west of Funchal. It is certainly worth while to determine why the pest is so serious in Egypt, and scarcely noticeable in Madeira. It may be that there is more damage in Madeira than I thought, but probably some efficient parasite will be found there. By collecting a quantity of the white material and placing it in a box, the parasites might be bred. That there is a parasite we know for certain, as my first sending from Funchal to Mr. Green could not be positively determined, consisting only of a mass of waxy secretion with fragments of the coccid, along with larvæ and pupæ of a parasitic Dipteron.

It is worth while to record at this time the occurrence of a really dangerous pest in Madeira, the *Aleurothrixus howardi* (Quaintance), on citrus in Dr. Grabham's garden in Funchal. It was determined for me by Dr. A. C. Baker of the U.S. Department of Agriculture. The infestation, while local, was very heavy, and if the insect spreads it may become a serious menace to the cultivation of oranges and related fruits.

Another potential pest found in Madeira is the rose-weevil *Pantomorus fulleri* (Horn). A single specimen was given to me by Mr. A. C. de Noronha, who found it in the vicinity of Funchal. It was identified by Dr. G. A. K. Marshall. As no other specimens have been found, it has perhaps not succeeded in getting established.

Definitions and Laws of Motion in the "Principia."

By Sir GEORGE GREENHILL.

MACH'S "Historical Lectures on Mechanics in its Development" ought to have a great influence on the treatment of the subject, with an English version from the Open Court Company. Mach has many a shrewd deep criticism to make on Newton's "Principia," and the present remarks are intended as an amplification of some of his scientific animadversion. It would have been worth his while to examine the previous state of the theory of dynamics to see what laws were current before the statement as given by Newton. These laws must have been enunciated, not only to give precision to the subject, but at the same time to correct and contradict previous fallacy and error, and it would be valuable to have a record in historical development.

The First Law must have excited incredulity, as contradictory to common observation of a body in motion, soon coming to rest of itself; and when the heavenly bodies were pointed at, a divine Primum Mobile was postulated to keep them going eternally, in the pious reflections of Aristotle, quoted in the former conventional manner at the end of the "Principia," and suggesting Napoleon's criticism of Laplace.

Axiomata sive Leges Motus. Lex I. Corpus omne perseverare in statu suo quiescendi vel movendi uniformiter in directum, nisi quatenus a viribus impressis cogitur statum illum mutare.

Similar statements can be traced in the writings of Aristotle and Plutarch. But it would be more instructive if we were told something of previous ideas contradicted in this Law, such as "A body in motion will come to rest of itself," as in observation of daily life, ignoring the reason and cause.

Lex II. Mutationem motus proportionalem esse vi motrici impressae, et fieri secundum lineam rectam qua vis illa imprimitur.

A vector change of momentum, *motus*, is indicated here; but the Law requires amplification in a commentary-corollary. *Motus* is quantity of motion, called momentum to-day, and *mutationem motus* requires to be qualified as time change, rate of change per time change, per unit of time; not per length or distance, which would imply energy or *vis viva*, an idea not extant in Newton's day.

Translated into our algebraical symbols, quantity of matter, *quantitas materiae*, of Definition I is denoted by W, lb. (in French it would be denoted by P, kg., for *poids*, *pondus*). Here W, the *Pondus* of our *Corpus*, is measured by weighing it in the scales, corrected for buoyancy of the air, and this is an operation susceptible to the greatest accuracy in physical measurement.

The velocity is v, in f/s (feet per second), so that the quantity of motion is Wv, lb.-ft. per sec., according to Definition II. Velocity v is not so easy to measure to equal accuracy as W.

Then, according to Law II, quantity of motion Wv acquired (from rest) under a force F acting for t seconds, is proportional to Ft (called the impulse), and expressed in a proportion, $Wv \propto Ft$, leaving the unit of force to choice.

The absence of the algebraical sign of equality, $=$, will be noticed as not employed in the "Principia." But in any numerical calculation, equality must be introduced by the appropriate constant factor.

Working with the practical gravitation Unit of Force, the only one in use up to fifty years ago, and still the only one capable of exact measurement, and taking our unit as the gravitation heft of a pound weight, the sign of variation, $\propto$, is replaced by the sign of equality, $=$, in the variation above by introducing g in the right place, and writing it in a homogeneous form

$$(1)\quad \underset{\text{(lb.)}}{W}\ \underset{\text{(sec.)}}{\frac{v}{g}} = \underset{\text{(lb.)}}{F}\ \underset{\text{(sec.)}}{t}$$

so as to verify when $F=W$, with $v/g=t$, $v=gt$, as in a free vertical fall of the body; $t=v/g$ being the number of seconds of descent to acquire velocity v, ft./sec.; in most practical problems it is near enough to take $g=32$, ft./sec.^{2}, in round numbers.

Then if s feet is the distance required to get up speed v from rest in t seconds, the average velocity

$$(2)\quad \frac{s}{t}=\frac{1}{2}v;$$

and multiplying into equation (1)

$$(3)\quad \underset{\text{(lb.)}}{W}\ \underset{\text{(ft.)}}{\frac{v^2}{2g}} = \underset{\text{(lb.)}}{F}\ \underset{\text{(ft.)}}{s}$$

and $\frac{v^2}{2g}=s$ in a free fall, where $F=W$.

And in a flying start, from velocity u,

$$(1)^*\ W\frac{v-u}{g}=Ft,\ (2)^*\ \frac{s}{t}=\frac{1}{2}(v+u),\ (3)^*\ W\frac{v^2-u^2}{2g}=Fs.$$

With these three equations, (1), (2), (3), any two of which imply the third, the young engineer may carry on for a long time in the linear dynamics, seen on the road and railway or in the air, up and down hill, getting up speed and checking it again with the breaks.

After that a variable force F may be introduced, as in Hooke's Law of the spring; a vibratory motion investigated, shown off in the pendulum, and seen in reciprocating masses of machinery, or a carriage body on springs. Here is theory enough to keep him going for a year.

Then after linear dynamics comes uniplanar dynamics, and the notion of rotation is introduced. A familiar illustration is always at hand in the door; every room has a door. The muscular sense of starting and stopping the rotation can be exercised; also in brandishing a stick, poker, bat, or club.

Angular inertia then requires measurement, although not mentioned in the "Principia," not even in "De motu corporum pendulorum" in Book II, or "In Horologiis et similibus instrumentis, quae ex rotulis commissis constructa sunt," where the *Corpus* may be the compound pendulum of a clock oscillating about its axle. Then Moment of Inertia requires definition,—the scalar sum of the product of every particle of the body by the square of its distance from an axis.

Thus, in "Matter and Motion," Maxwell reduces the uniplanar motion of any rigid body to an equivalent particle pair, rigidly connected, having the same total weight, the same centre of gravity, and the same moment of inertia about the centre of gravity.

The compound clock pendulum of Huygens is replaced in this way by its equivalent pair of particles, one being placed at O in the axle of suspension, and the other will be at P the centre of oscillation; and then OP is the length of the simple equivalent pendulum, a plumb bob P at the end of a thread OP.

Provided with these additional ideas in dynamics, the young engineer will be able to investigate the motion of the revolving parts of his machinery, such as a flywheel, a revolving shaft, a screw propeller, and the influence of the rotation of the wheels of a carriage.

Whatever the system of units employed, it is essential in the dynamical interpretation for g to be assigned its proper place, here under v. It must not be allowed to straggle and take cover under W, as in the old-fashioned treatise, where the author, to save trouble in writing and printing, adopted the mischievous delusive plan of replacing his W/g by the single letter label M, and then calling it the mass, a quantity *sui generis*, not its *Corpus*. He then wrote, with $v/t=f$, the acceleration, time rate of growth of velocity,

$$(4)\ F=Mf, \text{ with } W=Mg.$$

These relations are not seen in the "Principia-Elements," where g does not occur explicitly but is concealed in the length L of the seconds-pendulum, $g=\pi^2 L$. The "Principia" is chiefly kinematics; very little of kinetics until the second book, and then of experiments on fluid resistance, aways expressed in gravitation units.

Lex III. Actioni contrariam semper et aequalem esse reactionem: sive corporum duorum actiones in se mutuo semper esse aequales et in partes contrarias dirigi.

According to Maxwell, this Law—Action and Reaction are equal and opposite—amounts to no more than the definition of a stress, a pull or thrust, tension or pressure.

The sequel of Corollaries of Law III is important in introducing the ideas of vector composition, the conservation of momentum, and immunity of the centre of gravity to the internal actions and stress.

The Law was put forth probably as a contradiction to some accepted law in vogue before Newton, now forgotten. In some recent figurative language of the Press, we read "The pendulum is always swinging. Action, especially if violent, is apt to entail reaction." The former Law can still be traced in the popular idea current that the horse advances by pulling the cart harder than the cart pulls back. I remember a similar question about a double-headed express train; I was asked to explain what would happen if the second engine was going faster than the first: pulling harder I presume was meant.

The definitions come first in the "Principia," but we prefer to discuss them after the Laws, when the ideas they imply have been employed already in some tangible application, and so are capable of a better appreciation, and we can refer to them. Abstract definition requires to settle on some hard base of fact and comes after action in order of thought.

Definitio I. Quantitas Materiae est mensura ejusdem orta ex illius Densitate et Magnitudine conjunctim.

According to Mach, this is really no more than a definition of density, and *quantitas* is used as a synonym for *Corpus*, *Moles*, *Massa*, *Pondus*, five names to one entity. Nomina-Entia non sunt multiplicanda praeter quam necesse est.

Here *Corpus* would connote a body, *Moles* or *Mola* the bulk, *Massa* the aggregation of its stuff, and *Pondus* the quantity of its stuff measured out in a balance against standard lumps of metal called weights; revealed also roughly in the heft required to lift the body off the earth's surface.

The Greek equivalent for *Massa* would be *μάγμα*, *μᾶζα*, something kneaded and fashioned into shape; and the distinction in Latin between the words is brought out clearly in Ovid's lines (*A. A.* iii. 219):

"Quae nunc nomen habent operosi signa Myronis,
Pondus iners quondam duraque massa fuit";

assigning the quality of Inertia to *Pondus*.

But because Newton in this definition goes on to say—Innotescit ea (Quantitas) per corporis cujusque Pondus. Nam Ponderi proportionalem esse reperi per experimenta Pendulorum accuratissime instituta, uti posthac docebitur (meaning experiments to prove that the quality of the Matter does not matter)—it is rigidly insisted to-day in elementary instruction that *Pondus* should never be used except in this subsidiary sense of the accident of the gravitation of it, due to its situation on the surface of the earth. Moreover, we find Newton using *Pondus* elsewhere in both of the meanings of ordinary language; as, for example, in his preface—Unde solvitur in omni aptorum instrumentorum genere Problemata. Datum pondus data vi movendi. Sic pondera aequipollent ad movenda brachia Librae, quae oscillante Libra sunt reciproce ut eorum velocitates sursum et deorsum: hoc est, pondera, si recta ascendunt et descendunt, aequipollent, etc.

Definitio II. Quantitas Motus est mensura ejusdem orta ex Velocitate et Quantitate Materiae conjunctim.

This is the quantity called momentum to-day, our Wv, lb.-ft. per sec. And—Motus totius est summa motuum in partibus singulis—requires amplification to-day of "sum" to "vector sum."

Definitio III. Materiae Vis Insita . . . etc., is qualified as undistinguishable from *Inertia massae*, the *pondus iners* of Ovid, so here the two names are convertible, and one of them would serve.

The *Vis Impressa*, *Vis Centripeta*, *Vis centripetae Quantitas Absoluta*, *Acceleratrix*, *Motrix* (felt forcibly on the top of a motibus), and so on of the subsequent Definitions display a curious profusion of the word *Vis*, as much as in Hooke's vaunted Law: Ut Tensio sic Vis.

Vis, like moment, momentum, moment of momentum, moment of inertia, is a word too hackneyed in dynamics. A. N. Whitehead, in the "Concepts of Nature," uses the word moment to mean "all Nature at any instant." "Two moments of the same family are parallel." "A point flash of Nature is an event particle."

In Definition I, density is taken as the primary property of matter, although left undefined by Newton; while *Quantitas Materiae*, our W or P, is the product of density and volume.

The *Materiae Vis Insita* of Definition III is described as the same as *Inertia Massae*. This, however, is not the definition of *Massa*, but *Inertia*, although the two are treated as the same thing in modern interpretation.

Newton is not consistent with himself, as asserted, in always using *Pondus* as meaning the attraction of the earth on a body on the surface. As often as not he uses *Pondus* in the popular acceptation, as in the Act of Parliament, and a search in the "Principia" will reveal numerous instances.

This distinction, insisted on so carefully in modern instruction, was ignored in language and thought till about fifty or sixty years ago, when Absolute Measure was first introduced into dynamical teaching.

The artless definition of Mass, as the quantity of matter in the body, is near enough to serve in a dictionary, as a synonym in one line. It is merely the selection of a new name as a label in the long list already in Def. I. But a real definition will give at the same time the best way to measure the quantity. In a recent Royal Society memoir, on "mass determination" as the author is careful to call it, the question of its measurement turned on a "Study of the Balance, in its greatest precision, in a projective series of weighings of small masses," the most accurate of all physical operations we know.

Libra, sign in the Zodiac of the Balance, is an appropriate emblem of justice holding the scales.

It is contrary to the strict legal language of the Act of Parliament on weights and measures to start off with another artless definition—the weight of a body is the force with which it is attracted by the earth. At that rate, what is the weight of the moon, the sun? The definition is not supposed to apply to a body, so long as it is not terrestrial.

The attraction of the earth on the pound weight as the unit of force (gravitation) will never be abandoned by the engineer, as it is susceptible to the same degree of accuracy of measurement as the operation of weighing.

But when Tait took in hand the reform of dynamical teaching, he altered the equations in our form of (1), (2), (3), (4) in a new way, with the view of exterminating g. He discarded the old *sui generis* mass, with unit of g lb., and taking mass in its new meaning of the invariable quantity of matter in the body, he measured it in terms of the Act of Parliament unit of weight, the pound weight. This involved him in a change in the unit of force, to what was called a poundal, such that the engineer's gravitation unit of force, the pound (force), was equivalent to g poundals.

Tait's change merely amounted to labelling M the quantity formerly labelled W. But he insisted on retaining $W=Mg$, and so measuring what he called weight in poundals, contrary to the strict law of the Act, and rendering himself liable to a fine for every offence. Better if Tait had retained the letter W for lb., writing the equation $P=Wf$, and rejecting the useless $W=Mg$, as perpetuating the old *sui generis*, and breaking the law in the Act of Parliament.

This trouble of mere terminology would be exorcised if the habit was inculcated of always stating the unit of a dynamical quantity, as, for example, of a mass M, g, a weight W, lb. The engineer refuses to accept the poundal or to give a weight W in poundals. Scrap the name as useless, except for passing certain examinations.

To the masses in general the word mass implies a combination of bulk and density as in Definition I, as when we speak of mass of stuff, the mass of the earth—"Die Erde und ihre eigene ungeheure Last" (Mach). In ordinary language the mass will mean the multitude, or majority, as in the statement attributed to Herbert Spencer, "The mass of woman is insensible to gravity," which might mean a reminiscence of the ballroom floor; but this was before the women began to take themselves so seriously; and when we read the critic's snarl of the "Vast Mass of his writings consigned to Oblivion," Vast Mass here is forcible-feeble for *Major Pars*.

The word is spelt *Maas* in German; "Mass für Mass" is the title of the German version of Shakespeare's play "Measure for Measure."

Wegener's Hypothesis of Continental Drift.[1]

By PHILIP LAKE.

WEGENER'S hypothesis is based on the idea that the continental masses are patches of lighter rock floating and moving in a layer of denser rock, and this denser rock forms the floor of the oceans. Following, with a slight alteration, the terminology of Suess he calls the lighter material the Sial and the denser layer the Sima. Suess uses the words Sal and Sima, and thinks that the Sal covers the globe completely.

I shall not here discuss the possibility of Wegener's conception. He does not profess to explain completely why the continents should move, but he claims to have proved conclusively that such movement has taken place. It is the evidence on which he relies, and more particularly the geological evidence, that I propose to examine.

One of the arguments on which he lays great stress is derived from the relative frequency of different heights and depths upon the earth. His diagram of frequencies shows two well-marked maxima, one at about 100 metres above sea-level and the other about 4700 metres below it. Wegener concludes that two distinct surfaces standing at these two altitudes must have been involved in the subsequent movements. He assumes that these surfaces were originally level—or, more strictly, equipotential—and that they were the surfaces of the Sal and the Sima respectively. He holds that if originally there were only one such level, the deformation of that level could not produce two maxima and "the frequency must be regulated according to Gauss's law of errors."

In reality, if it is only a single level that has been deformed, it is improbable that the resulting altitudes

[1] Abridged from an address to the Royal Geographical Society on January 22.

will conform with the normal law of errors. The crust of the earth is not so constituted that each point can move independently of the rest, and the movements therefore are not analogous to the errors in a series of independent observations. According to the geological evidence the greater movements, which have most influence on the frequencies, are of a widespread character, and their general effect is to throw the surface into broad undulations. Upon these broader movements are superimposed the more intense but more local mountain-building movements.

Mr. G. V. Douglas points out in a paper to appear shortly in the *Geological Magazine* that if we start with a level, or equipotential, surface, and suppose it affected by movements of the types referred to, the resulting altitudes will necessarily give a frequency curve showing two maxima. The actual frequency curve is, in fact, perfectly consistent with ordinary geological conceptions and does not require the original existence of the two distinct surfaces postulated by Wegener.

Wegener imagines that at the close of the Carboniferous period the Sal formed one continuous patch covering about half the globe, and the Sima covered the rest. He professes that he has taken the forms of the existing land-masses, including their continental shelves: he has modified the present forms by unfolding the mountain ranges which have been raised since the Carboniferous period; and he finds that the different patches can then be fitted together into one continuous whole, like the pieces of a puzzle. It is evident, however, that Wegener has given free play to his imagination. In following the edge of the continental shelf he has allowed himself a very considerable amount of latitude, and he has not hesitated to distort the shapes of the masses. Few geologists who are familiar with mountain structures will attach much value to Wegener's estimates of the effect of Post-Carboniferous folding.

It is easy to fit the pieces of a puzzle together if you alter their shapes, but your success is no proof that you have placed them in their original positions. It is not even a proof that the pieces belong to the same puzzle. If Wegener's hypothesis rested solely on the evidence of fitting that he brings forward it might well be ignored. But there is more to be said for it than this.

In the Indian Peninsula the oldest fossiliferous deposits are of terrestrial origin and contain remains of plants and of reptiles. The flora is commonly called the Glossopteris flora and is very distinct from the contemporaneous flora of north-western Europe. There is a similar series of terrestrial deposits in South Africa and another in Brazil, both of which contain the Glossopteris flora and remains of reptiles. The Glossopteris flora occurs, moreover, in Australia, the Falkland Islands, the Antarctic continent, and in other parts of South America besides Brazil. In Wegener's reconstruction all these areas are brought together, and it is easy to understand why they should have a common flora and why that flora should be different from the flora of the distant Europe.

But the Glossopteris flora is found also in Kashmir, north-western Afghanistan and north-eastern Persia, Tonquin, northern Russia and Siberia. In Wegener's reconstruction all these areas lie far from the masses that he has grouped together in the south.

The Russian deposits are especially interesting. Not only do they contain representatives of the Glossopteris flora, but they also include reptiles of the same type as those which are found in South Africa, and several species of freshwater shells which are identical with those in the South African beds. Wegener's explanation has not by any means simplified the problem of the distribution of the Glossopteris flora and of the fauna associated with it.

In India, South Africa, South America, and Australia the system containing the Glossopteris flora begins with a boulder bed, which is universally admitted to be of glacial origin. These glacial deposits are now scattered over a wide extent of the earth's surface. Even if we admit movement of the pole, on the most favourable supposition the ice must have spread much farther towards the equator than the ice-sheets of the Pleistocene Glacial period ever did. Nor is it possible to invoke the aid of icebergs, for the associated deposits, except in the case of Australia, are all of terrestrial origin. With Wegener's reconstruction these difficulties disappear. The areas are grouped together and the pole may be placed conveniently in the middle of the mass.

But the boulder beds of this period are not limited to these areas. There is a boulder bed in the Salt Range which appears to be of the same age as the Talchir boulder bed of the Indian Peninsula. In north-western Afghanistan Griesbach found a boulder bed similar to the Talchir boulder bed, and in the beds overlying it he found several of the characteristic plants of the Glossopteris flora. According to Wegener's maps this boulder bed must have been deposited within 30 degrees of the equator of the period; and it cannot have been laid down at a great elevation, for the beds that conformably follow it include both marine and terrestrial deposits. Wegener's ideas have not very greatly reduced the area that must have been affected by the ice of the Permo-Carboniferous Glacial period.

There is another line of evidence that Wegener puts forward. There are five geological features, according to him, which occur on the two sides of the Atlantic and are re-united when the patches of Sal are fitted together.

The strike of the ancient gneiss of the Hebrides and northern Scotland becomes, he says, continuous with that of the gneiss of Labrador. The former, according to him, now runs from north-east to south-west, the latter from east to west. But according to the Geological Survey of Scotland the prevalent direction in Scotland is W.N.W.–E.S.E. or east to west. If Wegener's direction fits the other side the real direction does not.

The Caledonian folds of Scotland and Ireland, he says, become continuous with those of Newfoundland. But the Newfoundland folds are of considerably later date. If there was actual contact the earlier Scottish folding, in spite of its great intensity, must have ended abruptly at the line where separation was to take place ages afterwards, and on the other side of the line the commencement of the later Newfoundland folds must have been equally abrupt.

Farther south the Armorican folds of Europe, in Wegener's reconstruction, are continued by the Appalachian folds of North America, and no objection can be raised on the score of age. But a single coincidence of this sort has no value, for Wegener has adopted the simple plan of bending North America so that the

ends of the two systems meet and the folds fall into line.

In Africa, according to Wegener, the ancient gneiss foundation shows a sudden change of strike at the head of the Gulf of Guinea, and in South America there is a similar sudden change at Cape St. Roque. When the two continents are brought together the two different strikes and the line of separation between them become continuous. But in bringing about this coincidence he gives to the gneiss north of the Gulf of Guinea a north-east to south-west strike, and this is very far from the truth. Over a large part of the area the actual observations indicate that the prevalent direction is from north to south.

In South Africa a folded mountain range runs from east to west. In Buenos Ayres a folded range belonging to the same period has been described. According to Wegener one was the direct continuation of the other. But before they reach the western coast the South African folds, and the range that they have formed, turn to the north and run roughly parallel to the western coast. Wegener's explanation of this deviation is far from convincing.

It will thus be clear that the geological features of the two sides of the Atlantic do not unite in the way that Wegener imagines, and if the continental masses ever were continuous they were not fitted as Wegener has fitted them.

Obituary.

Prof. George Lunge.

ON January 3 Prof. Lunge died in his eighty-fourth year. For more than thirty years, from 1876 to 1907, he held the professorship of applied chemistry in the Polytechnic Institute of Zürich, directing the destinies of this department with characteristic energy, and with a success that attracted students from far and near, who sought to equip themselves for a career in industrial chemistry by a training under one who was recognised as the authority, especially in the branch of the manufacture of "heavy chemicals."

Dr. Lunge by his literary activity, as in other ways, contributed greatly to the advancement of chemical technology. His treatise on "Sulphuric Acid and Alkali," which has passed through several editions, is not only indispensable to the technologist, but is also replete with knowledge. As Mr. T. W. Stuart, himself a leader in the alkali industry in this country, and one of the few early contemporaries of Dr. Lunge, recently stated, "When you refer to these books on any obscure subject in the Alkali industry, you never go empty away, but always find in them a wealth of information."[1] A similar statement might justly be made in respect to Lunge's "Coal Tar and Ammonia," his "Technical Chemists' Handbook," and his "Handbook of Methods of Technical Gas Analysis," etc., each and all of which are essential to the equipment of the chemical technologist.

George Lunge was born at Breslau on September 15, 1839; from 1856 to 1859 he studied at the universities of Breslau and Heidelberg, graduating as Ph.D. In 1864 he came to England, with the object of obtaining technical experience. For a part of the twelve years spent in this country he was employed in the tar distillery of Messrs. Major and Co. at Wolverhampton, and in 1868 he was appointed chemist and manager to the Tyneside Alkali Company at South Shields. Dr. Lunge's efforts to obtain a footing in one or other of the twenty-six chemical works on the Tyne were at first far from encouraging, for, as Mr. Stuart tells us, a partner in one of the largest of these works offered Dr. Lunge the post of chemist at 1*l.* per week, which even at that time was but 2*s.* above the wage of a labourer! In the small works at South Shields Dr. Lunge continued until 1876, when he received the call to the chair of applied chemistry at Zürich. It is not without interest to note that his chief publications and researches deal with those phases of chemical industry, with the actual practice of which his sojourn in England had made him familiar.

At the time of his residence on Tyneside the Newcastle Chemical Society was founded, with Mr. Isaac Lowthian Bell (later Sir Lowthian Bell, Bart.) as its first president. Dr. Lunge became a member of this society, taking an active part in its proceedings and was elected president in 1872. In 1883 this society became merged into the Society of Chemical Industry and was formed into a local section of that society. However, Dr. Lunge, until the time of his death, retained his membership of the local section, using its Proceedings as the medium of publication from time to time of important scientific communications, and in many other ways evincing his sustained interest in its welfare.

The first Hurter Memorial Lecture was delivered in 1899 by Dr. Lunge before the Liverpool section of the Society of Chemical Industry, who selected for the subject of the lecture—"Impending changes in the general development of industry, and particularly the Alkali industry."

Drs. Hurter and Lunge, like many German chemists, *e.g.* Caro, Pauly, Otto Witt and others, came to England in the sixties of last century to gain a practical knowledge of British chemical industries. Dr. Hurter remained in this country and became identified with the Lancashire alkali industry, while Dr. Lunge returned to the continent, and based his teachings and writings on experience gained in the rival industry of the Tyne. Dr. Lunge had a complete command of the English language, writing and speaking it with ease and fluency. He married Miss Bowron, the daughter of a member of the firm of the owners of the Tyneside Alkali works at South Shields. P. P. B.

[1] *Chemical Trade Journal and Chemical Engineer*, January 19.

Prof. James Ritchie.

WE much regret to record the death of Prof. James Ritchie, Irvine professor of bacteriology in the University of Edinburgh. Up to the end of the summer term of 1922 Prof. Ritchie carried on his work with his customary energy and zest. In the holiday which he took during August in Perthshire, however, the early symptoms of his last illness began to give anxiety, and he died on January 28.

The record of Ritchie's life shows that since he

graduated in medicine in Edinburgh in 1888, at twenty-four years of age, there can have been few unoccupied hours. In 1889 a happy chance took him to Oxford to be assistant in general practice to Mr. Horatio Symonds. This post gave him a wide clinical experience, and at the same time he was able to develop his scientific bent in the laboratories of the Oxford Medical School. His mental and physical energy seemed inexhaustible. At first his available time was spent in original research in bacteriology: on the nature of bacterial toxins; the theory of germicidal action; the relation of toxic action to chemical constitution of the toxins; the reaction of immunity, etc. Following this, he undertook to teach the subject in the Medical School at the request of Sir Henry Acland, and while preparing for this he wrote, with Prof. Muir, the "Manual of Bacteriology," which was at once accepted as the standard English text-book in this subject.

After Sir John Burdon Sanderson was appointed to the Regius chair of medicine the teaching expanded into a full three terms course in pathology and bacteriology, and in 1902 Ritchie was appointed professor of pathology. In 1907 he returned to Edinburgh. As a result of his work in Oxford he had risen to the front rank in his subject. In Edinburgh he first carried on with great success the work of Superintendent of the Laboratory of the Royal College of Physicians, and in 1913 he was appointed to the newly established chair of bacteriology in the University. The Royal College, the Infirmary, and the University had endless profit from his labour.

For the interests of his subject in the medical schools of the country generally he did exceptional service as secretary of the Pathological Society, and as one of the editors of the *Journal of Pathology*. He held many offices, and his influence on the progress of medicine extended far, and in all his relations with his fellow-men his idealism and faithfulness called forth deep trust and affection. J. L. S.

Mr. W. W. Bryant.

WALTER WILLIAM BRYANT, whose death on January 31 we much regret to record, was born on January 9, 1865, at Forthampton, near Tewkesbury, where his father was a schoolmaster. He obtained a scholarship to Pembroke College, Cambridge, and secured a first-class in the Mathematical Tripos in 1887, and a second-class in the Natural Science Tripos of 1888. He was for a short time a master at Dulwich College, and in February 1892 obtained a post as assistant at the Royal Observatory, Greenwich. His work was mainly connected with meridian astronomy. He was a most expert observer with the transit circle and was largely responsible for raising the output from 5000 to 10,000 observations. This increase in the annual number of observations remains as a permanent result of Bryant's enthusiasm. His skill and enthusiasm was also shown in observations of double stars made with the 28-inch refractor. He continued to observe regularly with this instrument till the present time.

In the year 1904 Bryant was appointed senior assistant and given the superintendence of the magnetic and meteorological department. He took up magnetic work about the time when the instruments were being set up on a new site in an enclosure in Greenwich Park. He made a large number of absolute observations, and during the war had little, if any, assistance. He took a great interest in meteorology and was for many years on the council of the Royal Meteorological Society, being secretary from 1916 to 1920, and vice-president 1920–1922. His interest in astronomy did not cease when he took up meteorology. He was a regular attendant at the meetings of the Royal Astronomical Society and the British Astronomical Association, and was the author of a "History of Astronomy," published in 1907, and of biographies of Galileo and Kepler in the "Pioneers of Science" series.

Bryant's recreations were music and hockey. He was one of the founders of the hockey club associated with the Observatory and played regularly up to 1914, and from 1919 onwards he acted frequently as referee.

Bryant married in 1894 and had ten children, of whom one died in infancy, and one was killed in Gallipoli. He was at the Observatory until within a few days of his death. His colleagues were greatly shocked by the announcement of his death following an operation. He was conscientious and industrious and a very pleasant man to work with, who will be greatly missed by his astronomical and meteorological colleagues.

Mr. T. V. Holmes.

MR. THOMAS VINCENT HOLMES, whose death at the age of eighty-two occurred on January 24, was for long a familiar figure in the ranks of English amateur geologists. From 1868 to 1879 he held a temporary post on the Geological Survey, when he was occupied about Carlisle and was the author of the Survey's memoir on that district; he also took part in the mapping of the Yorkshire coalfield in collaboration with the late Prof. A. H. Green, and later had similar experience in the south-eastern counties. Though Mr. Holmes so soon relinquished his official duties for a more leisured life, he maintained to the end his keen interest in local geological problems. An acute observer, he did much useful work in recording new exposures in the south-east of England, and was one of the active members of the Geologists' Association and Essex Field Club, being president of the latter in 1886–1888. He was a fellow of the Geological Society and of the Royal Anthropological Institute.

Mr. Holmes contributed a considerable number of short papers to the Association and Essex Field Club; others appear in the Transactions of the Cumberland Association and the *Essex Naturalist*. His last association with the Geological Survey was a large share in the compilation of the memoir "On Thicknesses of Strata," published in 1916.

WE learn from *Science* that Dr. Fritz Wilhelm Woll, professor of animal nutrition in the University of California, died on December 6 at the age of fifty-seven. Dr. Woll was born and educated in Norway; on going to the United States, he became attached to the University of Wisconsin and was appointed assistant chemist in

1887, and later chemist, to the Wisconsin Agricultural Experimental Station. In 1906 he became professor of agricultural chemistry in the University, a post which he held until 1913, when he went to the University of California as professor of animal nutrition. Dr. Woll issued a number of valuable reports and bulletins on dairy matters and stock feeding while he was in charge of the research stations, and wrote, among other works, "A Book on Silage," "Testing Milk and its Products," and "Productive Feeding of Farm Animals," all of which have passed through several editions. According to *Science*, it was due mainly to Dr. Woll's efforts that the cow-testing associations, of so much importance to the dairy industry of California, have been developed and placed on a permanent basis.

MR. F. E. WESTON, the late head of the Chemistry Department of the Regent Street Polytechnic, died on January 4 after a long illness, and some account of his life and work appears in the *Chemical Age* of January 20. His death will be regretted by large numbers of chemists who came under his influence. Mr. Weston was the author of some sound and popular text-books, and in addition to his activities as a teacher he made several original investigations.

WE regret to announce the deaths of: Prof. Wilhelm Konrad von Röntgen, at the age of seventy-seven years; Mr. Bernard Bosanquet, on February 8, in his seventy-fifth year; and Dr. A. H. Fison, lecturer on physics at Guy's Hospital, London, and secretary to the Gilchrist Educational Trust, on February 5, at the age of sixty-five years.

THE *Chemiker Zeitung* of January 18 reports the death on December 6 of Prof. Luigi Marino-Zuco, of the Applied Chemistry Department of the Royal School of Engineers, Pisa.

Current Topics and Events.

THE recent decision of the Commissioners of Customs to enforce payment of the entertainment tax by the Committee of the West Highland Museum at Fort William in respect of an exhibition of local objects meets with some caustic comment in the February number of the *Museums Journal*. It is pointed out that the official regulations contemplate the issue of certificates of exemption for "entertainments" of this nature, and that the Board of Education encourages such temporary local exhibitions as the best means of securing the establishment of permanent provincial museums. Thus does one Government Department hinder the efforts of the other; and thus is constructed another argument for a properly thought-out State policy towards museums.

IN view of the withdrawal of oversea contributions to the Imperial Institute, a committee under the chairmanship of the Hon. W. Ormsby-Gore and including the High Commissioners of Canada, Australia, New Zealand, South Africa, and representatives of the Board of Trade, the Colonial Office, the Treasury, and the Associated Chambers of Commerce, has been appointed to investigate the position of the Institute. Mr. E. B. Boyd of the Colonial Office is acting as secretary to the committee. The terms of reference include a consideration of what functions now carried out by the Institute are considered essential and whether they should be transferred to other research organisations. Further, the committee has to consider to what extent the intentions of the founders of the Institute are being carried out and to suggest improvements which may be financially possible should it be recommended that the Institute continue on its existing basis. To us it seems astonishing that, as the Institute is largely concerned with the scientific study of the natural resources of the Empire, the committee does not include representatives of science, who alone are able to understand the significance and value of research aspects of the Institute's work.

THE General Electric Co. of America has had for several years a testing transformer which can produce a potential difference of a million volts between its terminals. We understand also that Prof. Millikan will be able to experiment with a million volts at his new laboratory at Pasadena. According to *La Nature* of January 20, the Compagnie Générale d'Électro-Céramique has decided to instal a battery of transformers in its test-room at Ivry which will give a pressure of a million volts for measuring the electric strength of insulating materials. With these high pressures it is possible to make commercial tests on insulators when arranged in series, as they are on high voltage transmission lines. The Americans have also used them for testing the efficiency of lightning safety devices, and for studying the phenomena which occur when a very high voltage discharge takes place on a network.

To any one concerned with public health, and more especially to those who have witnessed the ravages of small-pox among natives in our overseas possessions and the benefits conferred by vaccination, the exhibit of pictures and relics connected with Edward Jenner now on view at the Wellcome Historical Medical Museum, 54A Wigmore Street, W., cannot fail to be of interest. Here are shown many mementoes of this illustrious benefactor of mankind; an English country doctor, blessed with unusual powers of observation and animated by a scientific spirit, whose work, despite the efforts of cranks and detractors, will stand for all time. In addition to the large number of interesting objects forming part of the Wellcome Museum, special loan exhibits are displayed. Among them is the original pencil drawing of Jenner from life executed by Thomas Drayton, while there are many rare books and the original water-colour drawings of Kirtland showing the results of vaccination and variolation from day to day. Of the lancets Jenner used there are two with ivory points similar to those on which he sent dried lymph to India. The

coloured cartoon by Cruikshank entitled "The Cow-Pox Tragedy" only serves to remind us that the Jennerian method has survived the foolish and often venomous attacks made upon it for a century and more.

SEVERAL important Dinosaurian remains have lately been added to the collection exhibited in the Department of Geology in the British Museum (Natural History). A pelvis and tail of Trachodon, obtained by Mr. C. H. Sternberg from the Upper Cretaceous of Wyoming, U.S.A., have been mounted for direct comparison with the corresponding remains of Iguanodon from the Wealden of Sussex. The snout and jaws of a large Megalosaurian (Gorgosaurus), found by Mr. W. E. Cutler in the Upper Cretaceous of Alberta, Canada, have been placed close to the cast of the skull of Tyrannosaurus. The unique skull of Megalosaurus, discovered some years ago by Mr. F. L. Bradley in the Great Oolite at Minchinhampton, Gloucestershire, has been given by him to the Museum and is also now exhibited. It shows the bony core of a horn on the nose as in the American Jurassic Ceratosaurus. An interesting pelvis and femur of a small Megalosaurian found by Mr. S. L. Wood in the Lower Lias of Barrow-on-Soar, Leicestershire, and given by him, have also been mounted in the same case.

THE Decimal Association directed attention recently to the handicap imposed on foreign trade by the confusion which at present exists owing to the difference—amounting to twenty per cent.—between the Imperial and the American gallons, the former having the capacity of 277·2 cubic inches while the latter is the old wine gallon of 231 cubic inches. The Association therefore suggested that the British and American Governments should abandon their existing gallons and adopt the international litre as the common unit of capacity (100 litres are equal to 22 Imperial gallons). Anglo-American uniformity and a common basis for all international trade in liquids would thus be secured simultaneously. In this connexion it is interesting to note that the American Metric Association at its annual meeting on December 30 passed the following resolution: "Be it resolved that the American Metric Association heartily approves the recommendation for the immediate adoption of the litre as the common unit of capacity, believing that this step will not only facilitate trade between the two countries, but will also constitute a common basis for international trade and good-will; and it respectfully urges the British and American Government Departments, manufacturers, and merchants to effect this desirable reform."

ON February 17 occurs the bicentenary of the birth of the German astronomer Johann Tobias Mayer, who from 1754 to 1762 superintended the observatory at Göttingen. Mayer began life in a cartographer's office in Nuremberg, where he made improvements in map-making. His scientific work led to his appointment first to the chair of mathematics in Göttingen University, and then in 1754 to the charge of the observatory, which had just been furnished by George II. of England with a fine mural quadrant by Bird. Mayer's fame rests mainly on his lunar Tables, which were compared with the Greenwich observations by Bradley and Mason. Mayer died in 1762, and after his death a revised set of tables was sent by his widow to the British Government, who awarded her 3000*l.*, this being a part of the 20,000*l.* offered in 1713 for a method of determining the longitude at sea. His "Theory of the Moon" and his Tables were published in London in 1770 under the editorship of Maskelyne. He also made investigations on eclipses, colours, the motion of the stars, refraction, and terrestrial magnetism. His star catalogue was revised by Baily in 1830 and again by Auvers in 1894, while in 1881 Klinkerfues published a reproduction of Mayer's fine map of the moon which for a century had remained unsurpassed.

A CABLEGRAM from Calcutta to the *Times* announces the return of Mr. Kingdon Ward from a journey of eleven months in south-western China, Chinese Tibet, and northern Burma. Mr. Ward left this country early last year and first visited Mili in western Szechuan, where he found evidence of former glaciation, which he has already described in the *Geographical Journal*. His effort to proceed from Mili directly westward was frustrated by the disturbed condition of the country, and he returned south to Likiang and went north-westward to Atuntze. Thence he crossed passes between mountains, which he reports as ranging from 20,000 to 25,000 feet in height, along the Burmese-Yunnan frontier, between Major Bailey's route into Assam and that of Prince Henri d'Orleans from Tasa on the Salween into Burma. According to suggestions previously made by Mr. Ward the mountains of the Irrawadi-Salween divide are still rising, so that their glaciers are expanding instead of being on the wane as farther to the east. Apparently, however, in this area the glaciers have also decreased in size. Mr. Ward's observations on the structure of these mountains will be of special value. His primary work is botanical, and he has discovered remarkable new species of rhododendron and primula. Mr. Ward passed a little south of the area which, according to Mr. Forrest, was the original centre of distribution of the rhododendron. A fuller account of Mr. Ward's discoveries will be awaited with great interest.

A GREAT submarine earthquake occurred in the Pacific Ocean on February 3. As a first approximation, Prof. Turner locates the epicentre in lat. 50° N., long. 170° W., or about two hundred miles south of the Aleutian Islands. He remarks (*Times*, February 6) that other earthquakes occurred in the neighbourhood of this origin on January 30, 1914, and February 20, 1916. At Washington, D.C., and Fordham University (New York) the recording pointers of seismographs were thrown off the drums, indicating that the earthquake was one of unusual violence. Seismic sea-waves of considerable size swept over the ocean. At Hilo, in the Hawaiian Islands, which is about 2080 miles south of the origin, the waves were

reported to be twelve feet in height and to have drowned several fishermen in the harbour. With the above position for the origin, it is difficult to account for the fracture near Hawaii of the cable from Midway Island to Guam, unless, as is sometimes the case, there were two separate earthquakes, one to the south of the Aleutians and the other to the west of Hawaii—a supposition which receives some confirmation from a more recent telegram (*Times*, February 9) that the origin was about 2000 miles from Samoa.

A GERMAN correspondent writes: On February 9 Dr. G. Aufschlaeger, general director of the Dynamit A.G., formerly Alfred Nobel and Co., Hamburg, celebrated his seventieth birthday. Dr. Aufschlaeger was born at Jahnishausen, Saxony, graduated at Heidelberg and then became assistant lecturer at the Technical High School of Dresden. In 1882 he founded the dynamite factory of Muldenhütten, which was combined in 1884 with the dynamite works of Dresden; and in 1889 he became general director of the dynamite factory founded in 1864 by Alfred Nobel in Hamburg. Here he displayed an activity which was of the greatest importance for the whole industry of explosives. He brought about the combination of the principal German dynamite works and their co-operation with the chief foreign representatives of the industry. As the patents of Nobel for the manufacture of gelatin-dynamite from nitroglycerin and nitrocellulose, which belonged to his company, initiated a new epoch in the production of smokeless powder, he also succeeded in forming a syndicate with the manufacturers of gunpowder. This co-operation was of the highest importance technically, as it rendered possible the widespread distribution of new inventions and improvements. For the purpose of testing new inventions the scientific technical central offices in Neubabelsberg near Berlin were founded. In the construction of explosives works Dr. Aufschlaeger directed his attention towards securing the isolation of possible explosions and preventing their spread to other parts of the buildings. At the present time he is endeavouring to utilise the plant of the explosives works for peaceful purposes. "Vistra-wool," a substitute for cotton, produced from wood, is being manufactured by one of the dynamite works, and has been highly praised by experts.

IT is announced in the *Times* that in celebration of the 450th anniversary of the birth of the Polish astronomer Copernicus on February 19, a memorial tablet will be unveiled and a municipal scientific library bearing his name will be opened in his native town of Thorn.

THE new Research Laboratories of the General Electric Co., Ltd., Wembley, will be opened on Tuesday, February 27, at 2.30 P.M., when Lord Robert Cecil and Sir Joseph Thomson will deliver inaugural addresses.

THE annual lecture to the London Graduates' Section of the Institution of Mechanical Engineers will be delivered at 7 o'clock on Monday, February 26, by Prof. E. G. Coker, who will speak on "Photo-elastimetric Researches on Mechanical Engineering Problems."

WE notice in the programme of lectures for 1922–1923 of the Franklin Institute, Philadelphia, Pennsylvania, that Dr. Walter Rosenhain is lecturing to the Institute on the structure and constitution of alloys, and that in April Sir Joseph Thomson is to deliver a course of five lectures at Philadelphia on the electron in chemistry.

MAJ.-GEN. SIR FREDERICK B. MAURICE, Dr. Alexander Scott, and Prof. A. N. Whitehead have been elected members of the Athenæum Club under the provisions of the rule of the Club which empowers the annual election by the committee of a certain number of persons "of distinguished eminence in science, literature, the arts, or for public service."

THE following officers and members of council of the Royal Astronomical Society were elected at the anniversary meeting held on February 9:—*President*: Dr. J. L. E. Dreyer. *Vice-Presidents*: Prof. A. S. Eddington, Sir F. W. Dyson, Mr. E. B. Knobel, and Prof. H. F. Newall. *Treasurer*: Lieut.-Col. F. J. M. Stratton. *Secretaries*: Mr. H. Spencer Jones and Rev. T. E. R. Phillips. *Foreign Secretary*: Prof. H. H. Turner. *Council*: Prof. A. E. Conrady, Dr. A. C. D. Crommelin, Mr. C. R. Davidson, Prof. A. Fowler, Dr. J. W. L. Glaisher, Mr. P. H. Hepburn, Mr. J. Jackson, Dr. Harold Jeffreys, Prof. F. A. Lindemann, Mr. E. A. Milne, Dr. J. W. Nicholson, and Mr. J. H. Reynolds.

WE have received an address on advances in the metallurgy of iron and steel, delivered by Sir Robert Hadfield before the Cambridge University Engineering Society on January 25. The address, which was illustrated at the time by means of kinematograph and lantern slides and exhibits, ranges over a wide field, its subject being the importance of metallurgical discoveries to modern engineering. The scientific record of Cambridge and its school of engineering is taken as a text for a discourse on the technical applications of science, with special reference to motor-car engineering. In this connexion many passages are quoted and commented on from the recent autobiography of Mr. Henry Ford. An opportunity is taken to point out the exaggerated impression of German supremacy in chemical science which has been caused by our dependence on German text-books, and to urge that more attention should be given to the production of scientific compendia in the English language, and free from undue national bias. The address, which breathes a spirit of scientific enthusiasm, contains some interesting incidental notes on armour-piercing projectiles and similar subjects on which the author speaks with authority.

ACCORDING to the fourth annual report of the Scientific Instrument Research Association, the period for which Government grants on the present scale were guaranteed expires on June 30, but as there is in the case of the Association an unexpended balance sufficient to maintain the work for a sixth year, the Department of Scientific and Industrial Research has extended the period of the grant to June 30, 1924.

During the year 1921–1922 covered by the report, the Association has been engaged on researches on neutral, optical, and coloured glasses, on abrasives and cements for optical work, on the durability of glass, on phosphorescent material for X-ray use, on greases and wax mixtures, on lacquer, on the best wave for generation of X-rays, on regulation and focussing of X-ray tubes, on insulators, manganin wire, and on galvanometer coils. The work already done by the Association is bearing fruit, and firms engaged in instrument making are finding that the saving in their working costs owing to the adoption of methods suggested by the Association thoroughly justifies their financial support of it. We are glad to be assured that steps are being taken to secure from the industry adequate means to continue the work of the Association after the close of the Government grant period in June 1924.

We regret that a manuscript note on the corner of the first part of the *Zeitschrift für angewandte Geophysik* led the reviewer in our issue of February 3, p. 145, into stating that the price of the single part was 20*s*. The publishers, Gebrüder Borntraeger, have pointed out that this sum covers the whole of the first volume, and we hasten to make this correction in the interests of a publication which they have undertaken with their characteristic enterprise.

Messrs. Longmans and Co. have nearly ready for publication "Synthetic Colouring Matters: Vat Colours," by Prof. J. F. Thorpe and Dr. C. K. Ingold. It will deal with the history of vat dyeing, of synthetic indigo and the various analogues of indigo; the derivatives of anthraquinone, and the preparation of some of the vat colouring matters. Another book to be published soon by the same house is "Printing Telegraph Systems and Mechanisms," by H. H. Harrison, a text-book intended for the use of the designer, the administration official, the technical telegraphist, and the student of telegraph matters.

A new departure in the policy of the American Chemical Society is evidenced by the appearance (through The Chemical Catalog Co., Inc., New York), of a number of monographs on various branches of chemical science and the issue of a long list of projected volumes. The series is announced as "a serious attempt to found an American chemical literature without primary regard to commercial considerations." Among the monographs in preparation are: Shale Oil; Coal Carbonisation; Aluminothermic Reduction of Metals; The Chemistry of Leather Manufacture; Liquid Ammonia as a Solvent; Wood Distillation; Thyroxin; Extraction of Gasoline from Natural Gas; Refining Petroleum; The Structure of Crystals; The Properties of Metallic Substances; Solubility; Valence, and the Structure of Atoms and Molecules; Organic Arsenical Compounds; Absorptive Carbon; Chemistry of Cellulose; The Properties of Silica and the Silicates; Piezo-Chemistry; The Animal as a Converter; Cyanamide; The Corrosion of Alloys.

Our Astronomical Column.

The Great Red Spot on Jupiter.—Mr. W. F. Denning writes:—The planet Jupiter is now coming well into view and will rise at about midnight at the end of February. The Great Red Spot which has been certainly visible, though under rather different aspects, since 1857, is still to be distinguished.

It should be observed as often as possible during the ensuing spring months, and the times of its transit across the central meridian carefully recorded. Its rate of motion last year indicated a period of rotation equal to $9^h\ 55^m\ 38^s$. During the last few years the spot has exhibited a slackening of velocity. As a guide to telescopic observers the following times are given when this marking will be on or near the central meridian:—

	h.	m.		h.	m.
March 6	14	29	March 16	12	40
,, 8	16	7	,, 18	14	18
,, 10	17	45	,, 28	12	30

At the present time the spot precedes the zero meridian (of System II.) by about 3½ hours, and this is increasing. There is another long, dusky marking in nearly the same latitude of Jupiter which closely follows the eastern end of the Red Spot. This will also well repay observation. It has been visible since 1901.

Periodic Motion in the Three-body Problem.—Prof. Strömgren gives in No. 39 of the publications of the Copenhagen observatory a useful summary of the progress attained in recent years in the studies made there both in the restricted and the general problem of 3-bodies. (The former supposes one body infinitesimal, and the motion of the other two bodies circular.) The method used is that of mechanical quadratures, which is tedious and needs many successive approximations before periodic orbits are found, but it has the advantage of avoiding the mathematical difficulties involved in theoretical work.

The pamphlet also summarises the work of Sir G. Darwin and others. The connexions between families of orbits are traced, and it is considered that the treatment of the restricted problem with the selected mass-ratio is approximately complete. The orbits are divided into 16 classes comprising libration orbits about the 5 equilibrium points, 3 of which are in the line joining the finite masses, the other 2 are the equilateral-triangle points, which were at first merely theoretical, but later found exemplification in the Trojan group of minor planets.

The results illustrate various possibilities in the case of planets moving about a pair of suns. Each sun might have some satellites peculiar to itself, their motion, like that of our moon, being somewhat disturbed by the other. A figure-of-eight, encircling each sun in turn, is another possibility, while other orbs might pursue large orbits, in the form of distorted ellipses, outside both suns. But it must be remembered that periodic motion requires an exact adjustment of the initial speed and direction of motion. In most cases the orbits would not be periodic at all, but would undergo changes from one type to another.

A beginning has now been made with the study of the motion with all three masses finite. The case first studied was that of small librations about the 3 equilibrium points in a rotating line. This was subsequently extended to orbits of ejection or collision, in which 2 of the bodies are together at the beginning or end of the time considered. A case of 4-body libration is also sketched. No. 40 of the Copenhagen Publications deals with a special case of the 4-body problem, with 3 equal masses in a line, and the fourth infinitesimal.

Research Items.

THE SIKHS OF THE PUNJAB.—The present agitation among the Sikhs of the Punjab is critically discussed by a well-informed writer in the February issue of the *Fortnightly Review*. He points out that numerically the Sikhs constitute only 12 per cent. of the population of the Province, as compared with 51 per cent. Muslims and 36 per cent. Hindus, and that the revival of Sikhism in the period before the war was largely due to its encouragement by the British officers in Sikh regiments. The Sikh, by his aptitude for emigration, is much more open to foreign influences than the stay-at-home Hindu, and after the war he has suffered from a "swelled head." The recent agitation has centred round the management of the Gurudwaras or religious foundations, some of which fell into the hands of ill-conducted Mahants or Abbots, and has been favoured by the influence of outside agitation. We cannot enter into a discussion of the proposals the writer suggests for the control of the agitation and the redress of legitimate grievances. But as an episode in the history of one of the leading fighting races of India we may direct attention to this comprehensive review of a situation which, if not dealt with in a statesman-like way, may have serious consequences.

THE PLUNDERING OF ROYAL EGYPTIAN TOMBS.—While the recent wonderful discoveries in Egypt are engrossing public attention two writers in the February issue of *Discovery* have thrown welcome light on the subject. In the first article Prof. T. E. Peet tells us the little that is known of the history of King Tutankhamen, really a series of inferences from archæological remains. In the second article Dr. A. M. Blackman tells the strange tale of the plundering of the Royal Tombs at Thebes in the XXth and XXIst dynasties, as recorded in the Abbott Papyrus preserved in the British Museum, with sidelights from two Meyer Papyri, now at Liverpool, recently published with a translation and notes by Prof. Peet. In spite of the tragical course of the inquiry which followed the outrage and the horrible examination of the criminals by torture, the tale of the rivalry of the two Mayors, Peser and Pewer'ō, governors respectively of eastern and western Thebes, is graphic and characteristic: Peser acquired information of the robbery and thought it a good opportunity to pay off old scores against his hated rival, who was responsible for the protection of the royal sepulchres. Pewer'ō ultimately was discharged, but we may reasonably suspect that the charges were anything but groundless, and that the truth of them was being gradually forced on the Vizier Khamwesē who conducted the inquiry. In fact, it would seem that the maladministration of the necropolis had become so notorious that even heavy bribes could no longer make it worth the Vizier's while to continue his policy of hush. The tale, as a whole, shows that human nature in Egypt is now much the same as it was three thousand years ago.

SARSEN STONES.—The origin of the name given to these stones in the central region of the English Chalk seems still in doubt, but Sarsden village, near Andover, has been suggested as a possibility. The grey sandstone of which sarsens are composed is widely known through its use at Stonehenge; but the original bed in the Eocene series seems to have been completely broken up by denudation. The sarsens lie as relics on the surface, with detrital deposits worn from the Eocene strata and the Chalk, and an instructive photograph has now appeared in the Geological Survey Memoir on the country around Beaconsfield (Ordnance Survey, 1922, price 2*s*.). Here we are shown great blocks lying in the "clay-with-flints" of Buckinghamshire, and we learn that the stones are sought for by boring in the hope that the tool will strike on one. Following prehistoric practice, the builders of Windsor Castle gathered sarsens, and they are still the only useful stone to be found in the Beaconsfield district.

CITRUS FRUIT FROM SOUTH AFRICA.—Investigations on waste in export citrus fruit were carried out by Miss Thomson, and Messrs. Putterill and Hobson, during 1920 and were continued during 1921, and the results are embodied in a report, Bull. No. 1, 1922, Union of S. Africa, Dep. of Agriculture, Pretoria, 1922. Care in handling is perhaps the principal factor upon which elimination of waste depends. The slightest damage in packing or in the subsequent handling of the cases tends to induce discoloration and the development of moulds which spoil the fruit. Cargoes can be successfully shipped to this country not only in cold storage, but also in holds without cold storage provided they be properly ventilated and the fruit undamaged. Proper wrapping of the fruit in special wax tissue wrappers reduces wilting considerably. The best cold storage temperature lies between 43° and 50° F. Change in flavour is particularly induced by a temperature below 40° F., probably by killing the cells, thus allowing the acrid-tasting constituents of the skin to penetrate to the juicy part of the fruit.

BRITISH MYCOLOGY.—Volume 8, Parts I. and II. of the Transactions of the British Mycological Society contains Mr. Carleton Rea's presidential address; the views expressed by Mr. Rea as to the value of certain continental revisions of the systematic arrangement of the larger fungi will carry very great weight and, in the future, the microscope will certainly figure more prominently in the work of British mycologists. J. Line shows good reasons for regarding with suspicion the advent of the well-known "coral spot" fungus, *Nectria cinnabarina*, among a plantation of pruned red currants; the fungus apparently spreads slowly from dead spurs into the healthy tissues with disastrous effects ultimately. The paper by J. Ramsbottom upon orchid mycorhiza is reprinted in full from Messrs. Charlesworth and Co.'s catalogue; it is a scientific contribution of very general interest and at the same time a tribute to the memory of a remarkable orchid grower, the late Mr. Joseph Charlesworth. Among other papers should be noted Dr. M. C. Rayner's critical analysis of the claim recently made by Christoph to have raised healthy Colluna seedlings free from mycorhizal infection. W. B. Crow's account of that curious bacterial organism *Leuconostoc mesenteroides* is an interesting example of the significance that may attach in classification to the chemical constitution of a plant membrane: another step towards the distant day when chemical knowledge may be freely used to underpin the elaborate framework erected by the systematist.

BROWN BAST DISEASE OF RUBBER TREES.—A. Sharples has recently published (*Malayan Agricultural Journal*, vol. x. No. 6, June 1922) a résumé of recent experimental work in Malaya upon this problem, which is perhaps less urgent for the moment as the industrial depression has decreased the demand for rubber, and the one fact that seems firmly estab-

lished in connexion with this disease is that its spread coincides with efforts to get more latex from the trees. Sharples chronicles briefly the progress of investigations promoted by a representative Brown Bast Investigation committee formed in Malaya in 1918, but owing to changes of personnel this committee appears to have ceased to function in 1920 although investigations still proceeded. He also passes in critical review a number of papers recently published on the subject which were also noticed in NATURE for March 16, 1922 (vol. 109, p. 357). One general result of the investigations under the auspices of the committee is to strengthen the conclusion, also reached by Rands in Java, that while various organisms may be casually connected with the disease, none can be considered causal and the disease must apparently be definitely added to the list of pathological physiological conditions of obscure origin. In view of confident assertions by Keuchenius in Sumatra that bacterial inoculations produced a similar disease, this conclusion was very critically re-examined and comparative inoculations made with the organism used in Sumatra; the evidence against bacterial causation thus accumulated is very convincing. On the other hand, the Malayan experiments supply further experimental evidence that increased tapping of the latex, either by more frequent incision or by a wider cut, greatly increases the percentage of trees attacked by brown bast. Sharples reviews recent suggestions that various anatomical peculiarities may throw light upon the pathology of the disease. He regards the pockets of laticiferous tissues enclosed within wound cork, recorded by Sanderson and Sutcliffe, as after-effects of little value in elucidating the causes of the disease, and he points out that lignification and necrosis of sieve-tubes, such as is recorded by Farmer and Horne, may frequently be seen in perfectly healthy plants.

RAINFALL IN 1922.—The British Rainfall Organization, which now forms a part of the Meteorological Office, Air Ministry, has made a hurried scrutiny of the rainfall records for 1922 in time for insertion in the *Meteorological Magazine* for January, which is published in the middle of the month. Several thousand returns are said to have been already received and a selection has been made of those for which average returns exist; 280 such records have been examined and they afford sufficient data for the construction of a rainfall map. The rainfall for the individual months shows that the rain over the country as a whole was close to or above the average except in the autumn. The total was excessive over England in July, yielding locally more than double the average. October was exceptionally dry, the rainfall being in England and Wales 33 per cent. of the normal, in Scotland 59, and in Ireland 37 per cent. In England and Wales the only months with a deficiency of rain were May, June, October, and November. In Scotland there were six months with an excess and six months with a deficiency, the first seven months being wet with the exception of March. In Ireland there were only five months with a deficiency of rain; these were March, May, June, October, and November. The country as a whole had practically the normal fall for the year. The *Times* for January 29 had a detailed article on the rainfall of the past year, in agreement with its practice followed for many years past. It shows that 1922 was almost entirely devoid of remarkable features. Among the selection of records available the variations of rainfall registered in 1922 ranged from 115·25 in. at Seathwaite to 18·66 in. at Shoeburyness. The map giving the rainfall over the British Isles shows that there was a general deficiency of rain in Scotland and Ireland and a general excess over England, although in the extreme south-east, where the drought of 1921 reached its climax, the rainfall of 1922 was again below the average; but the deficiency apparently nowhere exceeded 10 per cent. The date given at head of Table II. for all columns except the average should be 1922 and not 1921.

RECENT VOLCANIC ACTIVITY IN S. AFRICA.—Dr. P. A. Wagner has written a very thorough and interesting memoir on "The Pretoria Salt-pan, a soda caldera," for the Geological Survey of S. Africa (Mem. No. 20, 1922, price 7*s*. 6*d*.). A saline lake some 25 miles north-west of Pretoria has long been used by natives as a source of common salt, and in recent years it has been worked on a commercial scale on account of the sodium carbonate in its waters. Excellent photographs are given of this *zoutpan* in its primitive and its industrialised conditions; but the most interesting of the numerous illustrations are those showing the form and the walls of the depression in which it lies. The author proves clearly that we are here dealing with a true caldera of explosion. If at any time a layer of volcanic scoriæ covered the broad cone of eruption, all traces have disappeared through denudation. It is far more probable that the walls were built up entirely of fragments exploded from the granite and dolomite that underlie the area. Their structure is seen in a number of cliff-sections, and the freshness of the whole ring suggests a Quaternary age for the paroxysm that actually domed up the granite cover and flung the fragments for 1700 feet on all sides from the central pipe. The perimeter of the caldera measures 11,100 feet. The saline layers from which the soda is mainly derived are a trona bed above and a bed of the rarer carbonate, gaylussite, in the muds below. There is a remarkable absence of sodium sulphate. Dr. Wagner gives good reasons for regarding the salts as of magmatic origin. Now that a kimberlite pipe in the Cape Province has been proved to be of post-Neocomian age (see NATURE, vol. 110, August 19, 1922, p. 262), evidence of volcanic outbreaks linking the southern region with the still active areas near the great lakes will be sought for with a lively interest. Folding sections and a map on a large scale accompany this comprehensive memoir.

PALÆOBOTANY AND THE GONDWANA CONTINENT.—Recent contributions to palæobotany will be found in the Quarterly Journal of the Geological Society, vol. 78, Part 3, where Prof. A. C. Seward describes carboniferous plants from Peru (pp. 278-83), and Seward and R. E. Holttum report upon Jurassic plants from Ceylon (pp. 271-77); and in the *Geological Magazine* (vol. 59, pp. 385-92, September 1922) Prof. Seward has a note upon fossil plants from the Tanganyika Territory. Dr. A. B. Walkom (Queensland Geological Survey Publication, No. 270) has recently commenced the publication of a monograph upon the Palæozoic Flora of Queensland, while the general issues and problems of distribution and of plant migration across regions of the globe that at the present day provide impassable oceanic or climatic barriers is raised by Prof. Seward in the Hooker lecture published in the Linnean Society's Journal for October 1922. These new palæobotanical data recorded above supply more facts for land areas that presumably were organically linked in Mesozoic times through the great Gondwana continent of which India now remains one of our most authentic relics. It is therefore interesting to note, from the

address of Prof. B. Sahni delivered at the Indian Science Congress in 1921 (Journal and Proceedings of the Asiatic Society of Bengal, vol. 17, No. 4, pp. 152-75), that Indian botanists are taking an interest in the Indian fossil flora, as yet but little explored since the earlier work of Feistmantel, embodied in the "Fossil Flora of the Gondwana System." Prof. Sahni points out that so far Indian strata have given little but plant impressions, but with the recent microchemical methods for the microscopic study of such impressions, developed in the Cambridge laboratories and demonstrated by Mr. J. Walton at the British Association Meetings at Hull, fossil impressions may become as valuable and as definite in the results they yield as the plant petrifactions permitting anatomical study.

MEASUREMENT OF VERTICAL DIMENSIONS WITH MICROSCOPE.—In the Journal of the Quekett Microscopical Club (Ser. 2, vol. 14, No. 88, November 1922) Mr. F. Addey gives a note on the measurement of the vertical dimensions of objects by the use of the graduated fine adjustment, in which he shows from mathematical considerations that the true thickness of the object is its apparent thickness multiplied by the refractive index of the mounting medium, the cover glass making no difference. This result has been confirmed by actual measurements.

FOCUS APERTURE RATIOS OF MICROSCOPE OBJECTIVES.—In the Journal of the Quekett Microscopical Club (Ser. 2, vol. 14, No. 88, November 1922) Mr. E. M. Nelson discusses the focus aperture ratios of microscope objectives. If the values of the numerical apertures of objectives now available be plotted against the magnifying powers the resulting graph reveals several inconsistencies. In the present paper a new set of power aperture curves drawn up on a definite plan are given for the construction of objectives. The ideal value for the power aperture ratio, obtained from a consideration of the resolving power of the eye, cannot always be realised in practice. This ideal ratio expressed as an "optical index" (that is 1000 times the N.A. divided by the initial magnifying power) is shown to be 25, and in the proposed curve for achromats the low powers up to $\frac{1}{5}$ in. have an optical index of 20, after which the optical index is reduced and the curve becomes steeper, rising to a $\frac{1}{2}$ in. with N.A. 0·9. In the apochromats the optical index in the curve is maintained at 20 up to a N.A. of 0·8. For oil immersion lenses the optical indexes have to be reduced, and the proposed curve begins with a $\frac{1}{2}$ in. of N.A. 1·0 (optical index 14·3) and ends with a $\frac{1}{12}$ in. of N.A. 1·4 (optical index 11·7). If such schemes of ratios of aperture to power were adopted the initial magnifying power and the numerical aperture would become practically synonymous terms and a lens could then be accurately designated by its numerical aperture instead of by the focus, thus avoiding ambiguity where different tube lengths are used.

CONTACT CATALYSIS.—No. 30 of the Reprint and Circular Series of the National Research Council contains the first report of the committee on Contact Catalysis. The report, which has been drawn up by Prof. Bancroft, gives a summary of recent work and suggests that the two fundamental things to be done in the study of contact catalysis are: (1) To determine in what cases definite intermediate compounds are formed and what they are; (2) To determine what bonds and contravalences are opened when adsorption takes place, and to show that the opening of these bonds and contravalences accounts for the formation of the reaction products.

BACTERIA AND CONDENSER CORROSION.—An investigation on the influence of the fermentation products of bacteria on corrosion in engine condensers, conducted by Messrs R. Grant, E. Bate, and W. H. Myers, originated during the systematic examination of possible factors in the causation of corrosion, particularly pit-hole corrosion, in condensers of two power-houses of the Government Railways and Tramways, Sydney, N.S.W. (Rep. of the Director-General of Public Health, N.S.W., for the year 1920, Sydney, 1922, p. 171). It had been noticed that tube failures often occur after a long period of shutdown, even when a condenser has previously been immune from trouble. The authors point out that condensers generally retain a considerable quantity of water, complete drainage never being obtained with the usual horizontal setting. This stagnant water always contains a very high proportion of free and albumenoid ammonia and nitrates. Various micro-organisms of ammonia-producing types were isolated from the circulating and stagnant waters of condensers. Plates of copper, brass, and zinc introduced into cultivations of these organisms underwent corrosion and pitting, photographs of which are reproduced. It is concluded, therefore, that the activity of micro-organisms as a factor in starting or causing corrosion must be seriously considered. If corrosion were a purely thermal or chemical effect, the pitting might be expected to increase steadily with temperature; actually, it is found to be more in evidence in low temperature condensers, which supports the micro-organismal theory.

FRENCH STREAM GAUGING APPARATUS.—In a notice recently issued from the gauging station of the University of Toulouse at Ponts-Jumeaux, a description is given of the log used by the French Service des Forces hydrauliques and the method of calibration adopted. The log is essentially a screw of a special form, attached to a revolving axis mounted on ball-bearings in the body of the log. The apparatus is designed in such a way that the axis lies in the direction of the current, and the screw encounters the liquid filaments in front. The relationship between the rotations n of the screw and the velocity v of the water is in the following form: $v=a+bn$. The determination of the speed of the screw in revolutions per second is carried out as follows. The axis of the screw engages by a worm in a cogged wheel, designed so that the screw makes N revolutions for a single revolution of the cogged wheel. This number, N, is fixed for any particular log and is generally equal to 25 or 50. A cam carried by the cogged wheel comes in contact at a fixed point of each turn with a spring plate connected with an insulated electric terminal on the body of the apparatus and thus closes an electric circuit actuating a bell. By measuring the time T, which passes between two consecutive signals, there is deduced therefrom the number of revolutions of the screw per second ($n=N/T$) and the movement of the water can be calculated. The coefficients a and b are determined in the process of calibration. For the purpose of calibrating the apparatus, a carriage with a platform is propelled at a certain speed while the instrument it supports is drawn through still water. During a sufficiently long series of runs, the speed of the carriage is related to the number of revolutions of the screw, and a curve, which is generally a straight line, can be drawn. A cement-lined channel 75 metres long, 2 metres wide, and 1 metre deep is used for calibration.

The Conduction of Excitation in Mimosa.

THE problem of the conduction of excitation in organisms is one that concerns both plant and animal physiologists, and any advances in our understanding of conduction in either kingdom should be of common interest to all. Yet certain recent discoveries concerning excitatory conduction in plants have so far not become very widely known.

The problem comprises essentially two questions: first, what is the nature of the excitation itself? and secondly, how is excitation at one point in an organ able to lead in turn to excitation at a neighbouring point? As to the first, there may perhaps be indications that excitation is something fundamentally similar in all protoplasm; but as to the second, it may well be that the link connecting the excitation of one point with that of the next is quite different in the case of different organs. In one case the nature of the link seems now to be well established—namely, in the case of species of the "sensitive" genus Mimosa, on which Dr. U. Ricca[1] has carried out a remarkable series of experiments.

As is well known, the spread of excitation in these plants is revealed mainly by the fall of the main petiole of the doubly compound leaf, the forward movements of the secondary petioles, and the folding together upwards in pairs of the leaflets. These movements can be brought about by injuring a leaflet, and also by inflicting cuts or burns on the main stem of the plant, which may lead to the spread of excitation along the stem and out over several leaves. It is principally on this conduction in the stem that Ricca has experimented.

The starting-point of his work is the proof that, as maintained long ago by Dutrochet, the path of conduction is the wood and not the phloem or cortex. To establish this he has made use, not of the well-known *Mimosa pudica*, but of *Mimosa Sepzazzinii*, in which it is possible to remove completely, in a ring round the stem, the tissues external to the cambium, thus laying bare the wood.

Such ringing does not prevent the excitation from passing, as is shown by the closure of the leaflets in the leaves above the ringed zone, after a part of the stem below the ring has been stimulated by cauterisation. Conduction can therefore take place without cortex. Further, by removing one longitudinal half of the stem and then, in the remaining half, prising off the extra-cambial tissues from the wood, he has been able to investigate the effects of stimulating the two separately. Stimulation of the strip of wood leads to movements in the leaves above, even after the pith has been scraped away, whereas stimulation of the strip of phloem and cortex does not. Since the latter are known not to be insensitive to stimulus, it follows that they must be unable alone to conduct the excitation effectively.

Next Ricca confirms the fact, already known, that conduction can pass through a zone of the stem that has been completely killed by heat, and he also shows that even when a zone of 4-5 cm. is maintained at a temperature above 150° F. this does not prevent the supply of water to the leaves above, nor the conduction of excitation. Going further, he divides the stem transversely and inserts the cut ends into the expanded ends of a narrow glass tube 8 cm. long and 1 mm. in diameter. An earlier experiment with a wider tube (1916, "a," p. 94) is less convincing. Cauterisation of the stem below the tube was followed by closure of the leaflets above it; and if the stimulus was strong, a greenish substance was seen to issue from the lower cut end, and slowly to spread up the tube. The time taken by the coloration to spread agreed roughly with the time apparently taken by the excitation to pass the tube (see schedules, *loc. cit.*, p. 119 *sq.*).

Already these results suggested that conduction takes place by the transference of a soluble stimulating substance excreted by the stimulated cells; for increase of permeability and excretion of liquid is known to accompany excitation in Mimosa and other plants. The final experiment in confirmation of this was the extraction of the substance by preparing in a small quantity of water a large number of transverse sections of stem. Other cut branches were then placed with their cut ends in the liquid thus obtained, and thereby excitation was found to be set up in them and to spread gradually up from the cut end towards the apex, as shown by the successive movements of their leaves.

It seems clear then that conduction both in the glass tube and in the wood of the plant must be brought about by the movement of a stimulating substance with the water current. It cannot be due to pressure changes; first, because it is too slow (in one case 55 cm. in 1¼ hours: average values for *M. pudica* are 8-15 mm. per sec. in the petiole and 2-3 mm. per sec. in the stem); and secondly, artificial changes in pressure of the water-supply to cut branches were not found to result in stimulation.

In agreement with this, factors increasing transpiration and so accelerating the ascent of water in the stem were found to increase the rate of conduction. Still, it may remain uncertain whether movements of the water current alone can account for all cases of conduction in these plants, particularly for basipetal conduction in the leaves. In *Mimosa Spezazzinii* this takes place only with difficulty, and Ricca considers it due to the excretion of liquid from the stimulated region, which is then sucked away in both directions by neighbouring unstimulated tissues. In *Mimosa pudica* basipetal conduction takes place rapidly and easily. Possibly the activity of other living tissues along the conducting zone may in some cases be involved, even if it is not necessary for conduction in the stem. It is also desirable that the results should be confirmed by other workers in warm countries.

Comparison may be made with the conduction of excitation in the cotyledon of a grass seedling, which also seems to involve a stimulating substance. In this organ, various stimuli, striking on the tip alone, bring about a responsive curvature in the elongating region below. The excitation conducted from tip to responding region can pass through a layer of gelatin, after the tip has been cut off and stuck on again.[2] It appears that Stark (*loc. cit.*) has extracted the stimulating substance concerned. An excitatory process capable of passing through gelatin has also been found by the present writer in roots.

But in these cases the mechanism of conduction in the tissues is still obscure, and probably different from that found in Mimosa. It appears that conduction may here take place in parenchymatous tissues, and it is checked by local application of anæsthetics and other physiological agents.

The Third Air Conference.

By Prof. L. BAIRSTOW, F.R.S.

THE Air Conference at the Guildhall, London, occupied four sessions — the mornings and afternoons of February 6 and 7—the first day being devoted to the reading of papers, and the second to their discussion. Of the papers read, that of greatest interest to men of science was by Sir Geoffrey Salmond, the Air Member for Supply and Research on the Air Council, on "The Progress of Research and Experiment." Before referring to this paper and the subsequent discussion, it is desirable to note some of the points made by Sir Samuel Hoare, the Secretary of State for Air, who spoke immediately after the opening ceremony by the Lord Mayor of London.

It was pointed out that the new Air Ministry had only been in office for three months and that the time had been all too short for the determination of a fixed policy. Later speakers emphasised the importance of the earliest possible declaration of policy, and were not wholly inclined to agree that, so long as the world is in a state of confusion and uncertainty, military aviation must have the first and principal call on the nation's purse. It was argued that civil aviation will have the same relation to the Air Force as the mercantile marine has to the Navy, and that the most economical expenditure of money would lead to a rearrangement of the vote so as to give a greater share to the commercial aspect.

It was argued by one speaker that private enterprise would be ready to find the capital for aerial transport when once it felt certain of a continuous and sympathetic policy on the part of the Air Ministry. The Secretary of State for Air had previously said that he was trying to develop a consistent civil aviation policy, and for weeks past had been considering schemes for its organic development.

The Conference was assured that the Air Ministry fully realised the importance of research and was anxious to foster it within the limitations imposed by finance. It is necessary to bear in mind the fact that the word "research" does not mean the same thing to all men, but in the sense in which that word is understood by men of science, there is a marked improvement in policy. It may be some time before the effects of the change are evident in results, for we have fallen on evil days, but it is to the good that the tide has ceased to ebb.

The Air Ministry organisation was described by the Air Member for Supply and Research in his opening paragraphs. He said: "Perhaps I may be forgiven if I describe to you our organisation for research, as I fear it is sometimes misunderstood. In the first place, there is the Air Ministry charged with the general direction of research. The Air Ministry is advised by the Aeronautical Research Committee, either on the initiative of the Air Ministry or on the initiative of the Aeronautical Research Committee, as to the problems to be solved, or as to the methods by which they should be solved. A representative of the Aeronautical Research Committee works in the Air Ministry and has direct access to me on all questions.

"The Aeronautical Research Committee does invaluable work in investigating all sorts of problems, and is wonderfully assisted in its work by the National Physical Laboratory and a whole body of scientists who give their services free to the nation, as well as by the great universities and consulting engineers.

"These organisations deal with the theoretical solution of air problems in the domain of pure research. But research cannot stop here; its practical application has to be considered, and this portion of the work is carried out by the Royal Aircraft Establishment at Farnborough and various experimental stations such as the Aircraft Experimental Establishment at Martlesham, and the Marine and Armament Experimental Establishment, Isle of Grain.

"A third organisation also exists, and that is the Aircraft and Aero-engine Constructors, who maintain most capable designing staffs who constantly bring forward solutions of problems, which enable us to step forward. I would be failing in my duty if I did not here acknowledge the debt this country owes to all these organisations, the joint efforts of which have undoubtedly brought our world position as regards research to a position second to none."

This constitutes the clearest statement of the organisation yet given, and it will be obvious to readers of NATURE that research as defined by the Air Member for Supply and Research has a much wider range than research as understood by men of science. In his interpretation, all technical development and experiment is included, and there is an absence of recognition of the usual criterion as to the fundamental or specific nature of the inquiry. It is in conformity with this definition that the Director of Research in the Air Ministry has wholly different functions from the Director of Scientific Research in the Admiralty. With adequate subdivision of funds and duties the matter of definition is unimportant, although the effect is the nominal allocation of a large sum for research, while in fact only a small fraction is devoted to scientific operations. There are marked indications of a welcome change, and that the advice of the Aeronautical Research Committee as to need for greater attention to fundamental inquiries is being acted on.

Sir Richard Glazebrook, chairman of the Aeronautical Research Committee, made during the Conference a special appeal for fundamental research, giving as subjects the study of the motion of viscous fluids from first principles, the provision for full scale research on airships should these again come into operation, and the study of the motion of aeroplanes in flight. All these forms of inquiry are greatly assisted by laboratory experiments and wind channel tests on models of aircraft.

The mathematical treatment of viscous fluid motion has not hitherto received any direct recognition by the Air Ministry, although the programme of the Aeronautical Research Committee leaves an opening for the staff of the National Physical Laboratory. The inquiry is, however, being fostered by the Department of Scientific and Industrial Research, and by the governors of the Imperial College of Science and Technology. Sir Richard Glazebrook asked for favourable consideration of such research by the Air Ministry.

The position of airship research was shown by the inquiry into the disaster to R38, but, in pursuance of instructions from the Air Ministry, the Aeronautical Research Committee has been unable to carry out its programme. A paper by Commander C. C. Burney on "The Establishment of a Self-Supporting Airship Service" has led to a reopening of the subject and to a divergence of opinion between the Air Ministry and Admiralty which is generally regretted. It appears that the Admiralty needs airships and is prepared to pay for them, but that the Air Ministry considers itself to be the proper body for supervising their construction. While it is hoped that the latter body will prevail, it would appear to require a change of policy and a real desire to retrace its disastrous past. Sir Alan Anderson expressed the point briefly when he asked whether it was really necessary to build airships at

considerable cost in order to put them into sheds and let them decay. Probably this action, typical of late policy, had much to do with the objections voiced by representatives at the Air Conference to the predominance of a military policy.

For heavier-than-air craft the feeling of the Conference appeared to be that the tide was turning, notably in the case of fundamental research. Sir Geoffrey Salmond mentioned many specific experiments and a few fundamental inquiries. Those relating to safety and trustworthiness received most attention in the discussion; but one item can be dealt with here. The dangers of flying are few so long as the engine is running perfectly, a state which cannot be relied on to persist for many consecutive hours. Failure of the power plant brings about a forced landing, and where the ground is unsuitable an accident follows. The dangers are increased by a peculiarity of an aeroplane when its wings are inclined to the wind at more than twenty degrees, for it then becomes uncontrollable. During the past year the trained and skilled experimental pilots of the Royal Aircraft Establishment, working in co-operation with a panel of the Aeronautical Research Committee, have modified an aeroplane and flown it at an angle of forty degrees. This is a momentous advance, for it leads to the hope that the danger arising from lack of control may be greatly reduced by further knowledge. It is therefore gratifying to find that the Air Ministry is ready to provide special aeroplanes solely for research by the Aeronautical Research Committee. It will be necessary to develop instruments for the inquiry, for we are still without adequate means of observation in flight except for the simplest types of motion, but again the Air Ministry is ready to give assistance.

Our lead in aeronautical research has been greatly reduced by America, but we appear to be regaining our power for progress, and a continuation of present policy may be expected to lead to that progress in aviation which is so clearly required for projected developments in civil aviation and for the defence of the realm.

Industrial Applications of the Microscope.

A MEETING of the Royal Microscopical Society was held on January 24, for the purpose of inaugurating an important departure in the history and attitude of the society towards national industry by the formation of a special section to deal with the industrial applications of the microscope.

Prof. F. J. Cheshire, president of the society, in his opening address, said that many years ago it had been seriously contended by some pessimistic fellows of the Society that its principal work of usefulness was done. Events of late years, however, had refuted that contention. Why, it was asked, have we a Royal Microscopical Society and not a Royal Telescopical Society? The answer was obvious. In the case of the telescope, practically any tyro could take out an instrument, of which he knew nothing or very little, direct it to the moon or any other object, and could, with a little practice, obtain the very best image which that telescope was capable of giving. The microscope could not be used in that simple way. It was the most complicated of all the optical instruments in common use, and it demanded, in its user, a considerable amount of optical knowledge and manipulative skill before it could be used efficiently and satisfactorily. The use of the microscope as a tool was extending day by day, advancing step by step with the recognition of the great importance of the study of micro-organisms and micro-structures. The Royal Microscopical Society had already carried out certain work in connexion with the industrial applications of the microscope. Sections, dealing with metallurgy, the manufacture of leather and of paper, had been in existence for a short time, but it was recognised that these specific sections made it difficult for the society to deal, as it ought to do, with the practical applications to new industrial work. In these circumstances it had been decided to form a large general section dealing with industrial applications of the microscope. The work of the section would be to encourage, in every possible way, the use of the microscope in industry and, at the same time, to give the most generous assistance to workers in the new fields of endeavour. Any one interested, whether a fellow of the Society or not, would be cordially invited to attend the meetings of the section.

A communication by Dr. F. J. Brislee dealt with the necessity of providing facilities for more definite instruction and training in the practical use and manipulation of the modern microscope, and outlined the manner in which the Royal Microscopical Society could be of assistance to those who had to use the microscope in industrial processes. Dr. Brislee further indicated the lines on which this practical training should proceed, starting with low-power work, the preparation, mounting, and examination of specimens, and proceeding gradually to the more difficult problems.

Dr. J. S. Owens (Superintendent to the Advisory Committee on Atmospheric Pollution) read a communication on atmospheric pollution. The importance of this subject to those working in large factories and to the general health of the community was insisted upon, and many interesting exhibits and lantern slides illustrated the means by which samples of polluted air were collected and examined. The method adopted is one in which a given volume of air is collected and then deprived of suspended matter by causing it to issue from the container as a jet and impinge against a prepared glass surface. Many unsolved problems were submitted to the meeting and suggestions invited as to the best methods of determining the actual nature of the particles of dust, oil, micro-organisms and other foreign matter collected.

In connexion with the leather-making industry, Dr. Browning suggested the more general use of the microscope in the control of the various processes. He showed sections of skin before and after puering, and stated that *if* it was necessary to remove the elastic tissue by puering, then this could be controlled only by the use of the microscope. Samples examined from several sources showed that different manufacturers were content with more or less removal of the elastic tissue. They could not all be right. Every detail in the preparation of specimens and the cutting of sections of leather was practically demonstrated by Miss Scott, and finished slides were exhibited.

Apparatus specially constructed for research work in many industries was demonstrated and described by Messrs. J. W. Atha and Co., R. and J. Beck, Ltd., The Cambridge and Paul Instrument Co., Ltd., Ogilvy and Co., J. Swift and Son, and W. Watson and Sons, Ltd.

Prof. Michelson's Work in Astronomical Interferometry.

MR. POST-WHEELER, who is on the staff of the American Embassy, attended at the annual general meeting of the Royal Astronomical Society on February 9 to receive the gold medal on behalf of Prof. A. A. Michelson, who was unable to be present himself.

Prof. Eddington gave a most illuminating address on the reasons of the award, explaining that the necessity for the great separation of the mirrors receiving the pencils of light from the stars was to give sufficient difference of length of path to enable the rays from the two extremities of a diameter of the star to be in opposite phase, so that the bright regions of the image from one extremity should fall on the dark regions of the other and so cause the fringes to vanish. It was mentioned that the method had been successfully applied to the measurement of the diameters of Jupiter's satellites, but the stars seem to have been considered hopeless, till recent physical work on the distribution of energy in the spectrum led to the conclusion that the red stars have such dull surfaces that the brighter ones must have appreciable discs in order to give so much light.

The actual figure had been calculated for Betelgeuse, and the observed diameter afterwards proved to be very close to it.

Some letters from Mr. Pease were read, in which he described the great practical difficulties that were incurred in applying the method of diffraction fringes, and the long-continued trials that were finally crowned with success. One of the earliest successes was the determination of the orbit of Capella. This gave, for the first time, a really accurate value of the mass and absolute magnitude of a giant star, which had already proved of use in the physical studies that were being made on these bodies.

A recent interesting development of the Betelgeuse measures was that the diameter came out different at different times, to an extent much beyond the probable errors of the measures. Attempts were being made to correlate these changes with the variable brightness and variable radial velocity of the star, but it will be necessary to carry on these measurements for some time before a definite conclusion could be reached.

Prof. Eddington went on to point out that the famous Michelson-Morley experiment, for which the Copley medal of the Royal Society was awarded in 1907, though not specially contemplated in the present award, might be considered as coming within its terms; for the measures were made by interference methods, and the question whether the movement of the earth through the ether could be detected was one of the highest astronomical interest. He knew that their medallist was disappointed at the negative result, but the whole of the system of relativity had been founded upon it, so that in his (Prof. Eddington's) opinion it was more fruitful than a positive result would have been.

In handing the medal to Mr. Post-Wheeler he asked him to transmit to Prof. Michelson their congratulations on his success and their good wishes for the long continuance of his fruitful labours. Mr. Post-Wheeler replied in a few suitable words expressing his sense of the pleasure it gave him to be there as the representative of America, and thanking the Society for the honour they had conferred upon his country in the person of Prof. Michelson.

University and Educational Intelligence.

BIRMINGHAM.—The Mitsui family of Japan has made a gift of 5000*l.* to the faculty of commerce. The Council has decided to apply the gift to the foundation of a chair of finance which, in view of the personal connexion of the Mitsui family with the university and of their generous contribution to its funds, is to be designated the Mitsui professorship of finance.

Mr. F. W. M. Lamb has been appointed assistant lecturer in pathology.

At the annual meeting of the Court of Governors, the principal appealed for more assistance from the districts surrounding the city. These districts at present contribute only 350*l.* per annum to the university as against 15,000*l.* given by the city, although half the students come from outside the city.

CAMBRIDGE.—Mr. J. B. S. Haldane, New College, Oxford, and Trinity College, has been appointed Sir William Dunn's reader in biochemistry. Mr. A. Hutchinson, Pembroke College, has been appointed University lecturer in crystallography. Dr. C. Shearer, Clare College, has been appointed University lecturer in embryology.

MANCHESTER.—The following lecturers have been appointed: physics, Dr. J. C. M. Brentano; engineering, Mr. H. W. Baker; biological chemistry, Mr. A. D. Ritchie.

OXFORD.—The vice-chancellor has appointed Sir Archibald E. Garrod, Regius professor of medicine and student of Christ Church, to act as deputy for the current term to Dr. Rudolph A. Peters, fellow of Gonville and Caius College, Cambridge, who has recently been elected Whitley professor of biochemistry in succession to the late Prof. Benjamin Moore.

The Weldon memorial prize, which was founded in 1907 by friends of the late Prof. Weldon, to perpetuate his memory and to encourage biometric science, has been awarded to Dr. Johannes Schmidt, director of the Carlsberg Laboratory, Copenhagen. This prize is awarded every three years, without regard to nationality, sex, or membership of any university, to the person who, in the judgment of the electors, has, in the six years next preceding the date of the award, published the most noteworthy contribution to biometric science. Previous recipients of the prize have belonged to St. Andrews, London, and Washington University, St. Louis. On one occasion it was awarded to a lady, Miss Ethel M. Elderton, fellow of University College, London.

SHEFFIELD.—Mr. W. Vickers has been appointed lecturer in education and master of method.

PROF. R. V. WHEELER, professor of fuel technology in the University of Sheffield, has been awarded the Greenwell medal of the North of England Institution of Mining and Mechanical Engineers, for his researches on coal.

THE first of a special series of lectures on "Master Minds and their Work," arranged in connexion with the London County Council's scheme of lectures for teachers, was delivered at King's College on February 14 by Dr. Charles Singer, whose subject was Leonardo da Vinci (1452–1519). The object

of the series is to illustrate, by the history of the work and influence of a few great men of various nationalities, the truth that in the study of the history of science is to be found a strong appeal to the spirit of community among men. It is suggested that this line of study will show that all nations have borne their share in building up the structure of knowledge according to the opportunities and civilisation of the times. Succeeding lectures are as follows:—February 21, Descartes (1596–1650), Prof. H. Wildon Carr; February 28, Newton (1642–1727), Prof. A. R. Forsyth; March 7, Pasteur (1822–1895), Sir D'Arcy Power; March 14, Helmholtz (1821–1893), Sir W. M. Bayliss; March 21 (at University College, Gower Street, W.C.1.), Darwin (1809–1882), Prof. Karl Pearson.

THE annual prize distribution was held at the Sir John Cass Technical Institute on Wednesday, January 31, and the awards were distributed by Sir Thomas Holland. The chairman of the governing body, the Rev. J. F. Marr, in giving a summary of the work of the Institute during the past session, stated that during this period a total of 1073 students had been in attendance—the highest figure yet attained. The year had not been an easy one, for financial considerations were and still are conspicuously in the foreground. The needs of technical education cannot be satisfactorily met without mutual trust and confidence between the public authorities and those administering the funds placed at their disposal, and without a full belief in the national value of technical education. Despite the restricted accommodation in the science departments, 31 students had been engaged in research work and five papers had been published, bringing the total number of original investigations issued from the Institute to 120. For the second year in succession a student of the metallurgy department had been awarded the first prize (Silver Medal) in the City and Guilds of London Institute examination in non-ferrous metallurgy.

THE Attorney-General, Sir Douglas McGarel Hogg, distributed the prizes at the Borough Polytechnic on Friday, February 2. Mr. J. Leonard Spicer, chairman of the governors, referred to the fact that Sir Douglas Hogg's father, Mr. Quintin Hogg, was the founder of the great Polytechnic in Regent Street, and Sir Douglas himself had throughout his life been associated with that Institute. Sir Douglas Hogg, in his address, said with regard to the work of the Institute, that it was not their desire to turn out a number of half-fledged amateurs to compete with the men in the workshops, but by technical instruction to enable those in the workshops to make themselves more efficient and to make greater progress in the industry to which they belonged. The policy of the governors in supplementing the experience of the workshop by trade instruction, and of selecting teachers who themselves had worked in the trades, is undoubtedly sound. The women's side of the Polytechnic is strong, and some of the activities of the Borough Polytechnic are unique in the south-eastern counties of England; the School of Bakery and Confectionery has no parallel, and the Department of Painters' Oils, Colours and Varnishes represents highly specialised and valuable technological departments. The Polytechnic has received valuable assistance from expert trade committees, trades unions, and associations of employers, in order to keep its work closely related to the current needs of industry. Principal Bispham, in his report, stated that both in quality and bulk the work of the past session was a record one and altogether a worthy tribute to the former principal, Mr. C. T. Millis, who has recently retired.

Societies and Academies.

LONDON.

Royal Society, February 8.—L. **Bairstow**, Miss B. M. **Cave**, and Miss E. D. **Lang**: The resistance of a cylinder moving in a viscous fluid. The equations of motion of a viscous fluid in the approximate form proposed by Oseen are taken as a basis for calculations of the resistance of a circular cylinder and the surface friction along a plane. In the case of the circular cylinder experimental information obtained at the N.P.L. is wholly suitable for the purposes of comparison with the present calculations. A resistance coefficient is found which is about 30 per cent. greater than that observed at the limit of the range of observation. Calculations for the plane show singularities at the edges, but lead to a resistance which is in rough agreement with experiment.—G. I. **Taylor**: The motion of ellipsoidal particles in a viscous fluid. According to Dr. G. B. Jeffery ellipsoidal particles immersed in a moving viscous fluid assume certain definite orientations in relation to the motion of the fluid. Ellipsoidal particles of aluminium and immersed in water glass take up such positions, but they take a long time to get to those positions. In the meanwhile they oscillate in the way indicated in Dr. Jeffery's analysis.—W. E. **Dalby**: Further researches on the strength of materials. In a new apparatus, an alternating load, push and pull, can be applied to a test piece in such a way that the curves of load and elastic extension are recorded photographically. The yield in tension and compression is found to be substantially the same, and the modulus of elasticity is the same, but alternating load is met by alternating response. When a load of either sign is removed the response is elastic, but imperfectly so. When a load is re-applied, but of opposite sign to the load removed, the response is mainly plastic. By means of a new instrument an alternating torque can be applied to a test piece in such a way that the curves of torque and elastic twist are recorded photographically. This shows that alternating torque is met by an alternating response in shear. It is possible to predict a practical fatigue limit from these diagrams.—Lewis F. **Richardson**: Theory of the measurement of wind by shooting spheres upward. A steel sphere, about the size of a pea or a cherry, is shot upwards from a gun, which is not rifled. The gun is inclined from the vertical towards the advancing air, and the tilt adjusted by trial until the returning sphere falls very close to the gun. The tilt is then some measure of a weighted average of the wind, in the region extending from the ground up to the maximum height attained. This height is found from the time of absence of the sphere. The observation of the tilt and time is repeated for greater and greater heights in succession. Mathematically speaking, the problem involves a "linear integral equation of the first kind," which is solved approximately by transforming it into a moderate number of algebraic simultaneous equations. In the general part of the theory an approximation which fails at the vertex of the trajectory is made. A special and sufficiently correct theory or a correction to the general theory meets this difficulty.—Ernest **Wilson**: On the susceptibility of feebly magnetic bodies as affected by tension. When magnetite is subjected to tensile stress of 50-130 kgrm. per sq. cm. as a maximum, the susceptibility for a given value of the magnetic force at first increases and then decreases as the specific load continuously increases, and exhibits a reversal point as in iron. The magnetic force at which the percentage increase in permeability has a maximum value is

less than the magnetic force at which maximum susceptibility occurs.—L. C. **Jackson** and H. Kamerlingh **Onnes**: (1) Investigations on the paramagnetic sulphates at low temperatures; (2) Investigations on the paramagnetism of crystals at low temperatures.—W. D. **Womersley**: The specific heats of air, steam, and carbon dioxide.—D. W. **Dye**: The valve-maintained tuning fork as a precision time standard. The valve-maintained fork is steady in frequency to a degree beyond that required for most purposes. The most serious cause of variation of frequency is that due to temperature. The temperature must be kept constant to 0·1° C. if accuracy to one part in a hundred thousand is required. By the use of a special steel ("elinvar") having a very small temperature coefficient of elasticity, it is probable that the variation of frequency with temperature could be reduced to one-tenth that of ordinary steel forks. The other factors causing variation of frequency are not themselves variable without attention to an extent which would cause a variation of more than a very few parts in a hundred thousand. By suitably choosing the capacities and the anode voltage, a variation of voltage of ±10 per cent. will cause a change of only about one part in a million in frequency.

Geological Society, January 24.—Prof. A. C. Seward, president, in the chair.—S. H. **Haughton**: On reptilian remains from the Karroo beds of East Africa. Three specimens of a small fossil from black shale from the middle of the Karroo formation, near Tanga, on the coast of Tanganyika Territory, represent a new genus and species of aquatic reptile resembling Mesosaurus. It may be regarded as an aquatic adaptation of Youngina. If so, the shale at Tanga is approximately of the same age as the Middle Beaufort beds of South Africa.—Rev. C. **Overy**: Glacial succession in the Thames catchment-basin. A definitive succession-grouping for high-level gravels of the Thames catchment-basin is established. A norm series with effective nomenclature for the Berkshire-Oxfordshire area is suggested, namely, P_{350}, P_{300}, P_{265}, P_{230}, P_{210}, P_{160}, P_{135}. Grading and analysis in the Hampshire and London areas result in the establishment of the norm series for the whole river-system. In this way light is thrown on the age of the Goring Gap, the mode of deposition of the plateau-gravels, glacial succession in the Thames basin, and the bearing of the distribution of drift constituents on the history of the Thames river-system. Evidence is given for the course of the pre-Pleistocene Thames, for the continuity of the Evenlode, Goring Gap, Henley Gorge, Colne-Lea divide, and Essex-coast system.

Physical Society, January 26.—Dr. Alexander Russell in the chair.—C. **Chree**: A supposed relationship between sunspot frequency and the potential gradient of atmospheric electricity. Dr. L. A. Bauer has concluded that both the range of the diurnal inequality of atmospheric electricity potential gradient and the mean value of the element for the year increase and diminish with sunspot frequency. The conclusion was based on observational data from the Ebro Observatory, Tortosa, Spain, between 1910 and 1920. Kew electrical data from two periods of years, the Ebro data utilised by Dr. Bauer, and magnetic data from Kew Observatory were treated mathematically. The results indicate that if a relationship of the kind exists, the sunspot influence must be very much less in the case of atmospheric electricity than in that of terrestrial magnetism.—J. J. **Manley**: A further improvement in the Sprengel pump. The pump was described in Proc. Phys. Soc., vol. 34, p. 86. The present improvement provides a mercury seal during periods when the pump is out of use, whereby the formation of fresh-air skins is prevented.—D. **Owen**: Null methods of measurement of power factor and effective resistance in alternate current circuits by the quadrant electrometer. The methods are extended to high-tension circuits. The usual formula for the quadrant electrometer is applicable only when the needle is maintained at its mechanical and electrical zero.—C. E. **Prince**: An electro-capillary relay for wired wireless. The relay is intended for use with a calling device in connexion with high-frequency currents acting as carrier waves for telephony over power-mains. The high-frequency current is rectified and passed through a thread of mercury which is contained in a capillary tube, and is in contact at each end with some acid containing platinum leads. The passage of the current causes the mercury thread to move. The capillary tube is arranged horizontally on a beam which, as soon as the mercury moves, overbalances in consequence of the weight of the latter and closes the circuit of a call bell or lamp. In series with the thread and with a rectifier is arranged a condenser in which the charge that has passed round the circuit is stored, and after the call this charge is sent through the mercury and acid in the reverse direction; this restores the mercury to its original position. If the call be unanswered the same result is produced more slowly by a high-resistance leak. The instrument responds to currents of 4 or 5 or even 2 microamperes. The total movement appears to be proportional to the coulombs which pass.

Linnean Society, February 1.—Dr. A. Smith Woodward, president, in the chair.—Sir Sidney F. **Harmer**: On Cellularine and other Polyzoa.—Sir Nicholas **Yermoloff**: Notes on Chætoceros and allied genera, living and fossil. Chætoceros is highly differentiated for pelagic life; it occurs in the planktons of the colder seas, sometimes, especially in spring, in colossal numbers. Some 100 living species have been described, but only 6 or 7 are common in the planktons. The parent cells, each consisting of two valves with a hoop between them, form colonies, holding together by means of long setæ; they have thus great floating capacity. Several species develop internal organs, covered with a thick siliceous wall, called statospores, inside the mother-cells. Their function is not known. The mother-cells, or colonies, as such, never appear in any fossil marine deposits, though the spores appear fairly often. The spores of Chætoceros have been taken in the past as separate Diatom genera, and classified and named as such. Fossil spores of Chætoceros are frequent in Miocene diatomaceous earths. The most common form is Syndendrium Ehr., the spore of *Chætoceros diadema* Gran, which is very common in the planktons.—H. L. **Clark**: Some echinoderms from West Australia.

CAMBRIDGE.

Philosophical Society, January 22.—Mr. C. T. Heycock, president, in the chair.—Sir Joseph **Larmor**: (1) The stellate appendages of telescopic and entoptic diffraction. (2) Can gravitation really be absorbed into the frame of space and time? (*see* NATURE, February 10, p. 200).—H. F. **Baker**: The representation of a cubic surface upon a quadric surface.—H. **Hartridge** and F. J. W. **Roughton**: Measurements of the rate of oxidation and reduction of hæmoglobin. Methods were devised for estimating instantaneously the percentage saturation of hæmoglobin with oxygen, for mixing instantaneously either reduced hæmoglobin with an oxidising agent or oxyhæmoglobin with a reducing agent, and for preparing rapidly the reduced

hæmoglobin solution in large quantities. Oxidation takes place exceedingly rapidly, in approximately one-hundredth part of a second at 10° C., whereas reduction takes approximately one second. The rate of reduction agrees with the formula deduced on the assumption that the reaction is mono molecular, and the ratio of the rates of the two reactions was of the same order as the value of the equilibrium constant. In the body both changes take place at temperatures considerably higher than those used. They would be expected therefore to be even faster (some ten or twenty times) in the body than in these experiments.—J. T. **Saunders**: A method of measuring the carbon dioxide output of aquatic animals. The method is based on the fact that, from measurements of the hydrogen ion concentration of solutions of bicarbonates of known concentration in equilibrium with carbon dioxide, the tension, and so the amount dissolved, of carbon dioxide can be calculated.—Miss D. **Eyden**: Changes in the specific gravity of *Daphnia pulex* L. *Daphnia pulex* increases in specific gravity immediately after feeding and diminishes after starvation. These changes may account for the vertical movements of forms living in the plankton.

DUBLIN.

Royal Irish Academy, January 22.—Prof. Sydney Young, president, in the chair.—A. K. **Macbeth**: The action of sulphur chloride on ammonia and on organic bases. The action of sulphur chloride on ammonia was examined quantitatively. No sulphur nitride hitherto unknown was isolated, but a new derivative containing sulphur, nitrogen, and hydrogen was described. This compound, which it is proposed to call hexasulphamide, appears to have the composition S_6NH_3. The action of sulphur chloride on the aromatic amines was examined qualitatively, and the course of the reaction at low temperatures was studied with *o*-toluidine, N-dithiotoluidine being isolated.—T. P. C. **Kirkpatrick**: Charles Willoughby, fellow of the King and Queen's College of Physicians. In 1690 Dr. Charles Willoughby wrote a paper dealing with the political economy and vital statistics of Ireland which he sent to William King, then Bishop of Derry. It was published in full in the Proceedings of the Royal Irish Academy in 1857. Recently a letter from King has come to light in which he gives information about the condition of the people in the country, and the difficulties in collecting statistical information. Some letters from Willoughby to King throw an interesting light on medical practice in Dublin at the end of the seventeenth century. While studying medicine in Padua, where he graduated M.D. in March 1663/4, Willoughby made a collection of botanical specimens, which he afterwards presented to Merton College. Willoughby was one of the founders, and was the first director of the Dublin Philosophical Society, and in 1675 he was elected president of the College of Physicians. He died in 1694.

PARIS.

Academy of Sciences, January 22.—M. Albin Haller.—G. **Bigourdan**: The co-ordinates of the Observatories of Muette and Passy.—L. **Lecornu**: The orbit of Mercury. A development of a suggestion of M. Haag in a recent note, showing that the displacement of the perihelion of Mercury can be explained by adding to the Newtonian attraction a small tangential force and a small force directed towards the sun.—L. **Maquenne**: Remarks on a recent communication of MM. P. A. Dangeard and Pierre Dangeard. A discussion of some consequences of the observation that leaves of *Aucuba japonica* suffer no loss of vitality over a period of several months if preserved in a vacuum and exposed to light.—E. **Leclainche** and H. **Vallée**: Vaccination against symptomatic anthrax by toxins. A discussion of the difficulties and limitations attending vaccination by toxins derived from *B. Chauvoei*.—A. **Blondel**: The determination as a function of the initial conditions of the free oscillations of alternators working in parallel and connected individually with motors with theoretical regulation, instantaneous and fixed. Application to synchronous motors.—A. **de Gramont**: Observations on the structure of the chromium spectrum. Directing attention to the recent experimental confirmation by M. Catalan of the theoretical views propounded by the author in November 1922.—C. **Guichard**: Polar figures reciprocal with respect to a sphere.—A. **Guntz** and **Benoit**: The heat of oxidation of the metals of the alkaline earths. A repetition of earlier work with purer material. The heats of oxidation of calcium, strontium, and barium were found to be 152·7, 141·8, and 134·04 calories respectively.—A. **Bigot** and Mme. E. **Jérémine**: New observations on the geology of the Hague (Manche). M. Philippe Glangeaud was elected corresponding member for the section of mineralogy in the place of the late Otto Lehmann.—Erwand **Kogbetliantz**: The double means of Cesàro.—S. **Stoilow**: Continued functions and their derivatives.—C. **Kuratowki**: The effective existence of functions representable analytically every Baire class.—M. **Alliaume**: The nomographic resolution of systems of equations.—H. C. **Levinson**: The Einstein gravitation of systems.—Emile **Picard**: Remarks on the preceding communication.—G. **Poivilliers**: A method of stereoscopic representation of topographical surfaces.—Paul **Dienes**: The relativist electromagnetic theory.—G. **Gire**: The dissociation of potassium chloro-iridate.—Pierre **Steiner**: The ultraviolet absorption spectra of the alkaloids of the isoquinoline group. Narcotine, hydrastine, and hydrocotarnine. The ultraviolet absorption spectrum of narcotine is determined by the benzene ring of its molecule; the isoquinoline nucleus only displaces the absorption towards the red end. For papaverine, on the contrary, it is the isoquinoline and not the benzene ring which is the determining factor.—A. **Catalan**: The structure of the arc spectra of molybdenum, selenium, and chromium.—F. W. **Klingstedt**: The ultraviolet spectra of aniline and the toluidines. The results are given in diagram form, and differ considerably from the data obtained by earlier workers in the same field.—Mlle. **Chamié**: The ionisation produced by the hydration of quinine sulphate. A direct connexion between ionisation and the amount of water taken up is proved.—A. **Bouzat**: A class of unstable hydrates known as hydrates of gases. Confirmation of M. Villard's hypothesis. Many gases form hydrates possessing the following properties: their formula is $M.6H_2O$, they are unstable, formed with a small heat evolution starting with the constituents in the solid state, and on dissociation lose all the six molecules of water at once.—L. **Franchet**: A new industrial material of the neolithic age. An account of the discovery of neolithic agricultural implements made of polished sandstone, at Piscop.—Pierre **Lesage**: The persistence of the characters produced in plants by salt.—Antonin **Němec** and Kvapil **Karel**: The biochemical study of forest soils.—V. **Crémieu**: The growth of plants and the principles of physics.—L. M. **Betancès**: The ageing of the hæmatic cell.—G. **Ramon**: Dissociation of the diphtheria toxin-antitoxin complex and the recuperation of the antitoxin.—F. **Heim**, E. **Agasse-Lafont**, and A. **Feil**: The rôles of lead and turpentine in the professional

pathology of painters. From a comparative study of painters divided into two groups, one using paints containing lead and the other working with lead-free paints, the authors conclude definitely that it is not turpentine but lead and its compounds which are the cause of renal lesions and hypertension in painters.

Official Publications Received.

Abstract-Bulletin of the Nela Research Laboratory, National Lamp Works of General Electric Company, Cleveland, Ohio. Vol. 1, No. 3, October. Pp. ix+303-521. (Cleveland.)

Summary of the Annual Report of the Naval Observatory for the Fiscal Year 1921. (Appendix No. 2 to the Annual Report of the Chief of the Bureau of Navigation.) Pp. 53. (Washington: Government Printing Office.)

Nauka Polska: jej Potrzeby, Organizacja i Rozwój. (Polish Science: its Needs, Organisation and Progress.) III. (Year-Book of the Mianowskie Institution for the Promotion of Scientific Research Work.) Pp. vi+280. (Warszawa.) 150 marks.

Report of the Department of Mines for the Fiscal Year ending March 31, 1922. (Sessional Paper No. 15.) Pp. iii+48. (Ottawa.) 5 cents.

Department of the Interior: United States Geological Survey. Mineral Resources of the United States in 1921 (Preliminary Summary). Pp. iv+102A. (Washington: Government Printing Office.)

Crichton Royal Institution, Dumfries. Eighty-third Annual Report, for the Year 1922. Pp. 49. (Dumfries.)

National Museum of Wales. Fifteenth Annual Report (1921-22) presented by the Council to the Court of Governors at a Meeting held in Cardiff on the 27th October 1922. Pp. 35+6 plates. (Cardiff.)

Diary of Societies.

SATURDAY, FEBRUARY 17.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Ernest Rutherford: Atomic Projectiles and their Properties (1).

MONDAY, FEBRUARY 19.

ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge, Kensington Gore), at 5.—Dr. R. L. Sherlock: The Influence of Man as an Agent in Geographical Change.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—F. P. Sexton and others: Discussion on Esprit de Corps.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—H. V. Lanchester: Architecture and Architects in India.

ARISTOTELIAN SOCIETY (at University of London Club), at 8.—C. E. M. Joad: The Problem of Freewill in the Light of Recent Developments in Philosophy.

FARADAY SOCIETY (at Chemical Society), at 8.—Prof. A. W. Porter and J. J. Hedges: The Law of Distribution of Particles in Colloidal Suspensions with Special Reference to Perrin's Investigations, Part II.—D. B. McLeod: A Relation between the Viscosity of a Liquid and its Coefficient of Expansion; The Viscosity of Liquid Mixtures showing Maxima; A Relation between Surface Tension and Density.—M. Cook: Crystal Growth in Cadmium.—F. H. Jeffery: Electrolysis with an Aluminium Anode, the Anolyte being (1) Solutions of Sodium Nitrite, (2) Solutions of Potassium Oxalite.—S. D. Muzaffer: Electric Potential of Antimony-Lead Alloys.

ROYAL SOCIETY OF ARTS, at 8.—Dr. H. P. Stevens: The Vulcanisation of Rubber (Cantor Lectures) (3).

TUESDAY, FEBRUARY 20.

ROYAL STATISTICAL SOCIETY (at Royal Society of Arts), at 5.15.—J. Hilton: Statistics of Unemployment derived from the Working of the Unemployment Insurance Acts.

INSTITUTE OF TRANSPORT (at Institution of Electrical Engineers), at 5.30.—F. Bushrod and J. F. S. Tyler: Modernisation of Passenger Railway Stations.

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—The Secretary: Report on the Additions to the Society's Menagerie during the Month of January 1923.—Prof. H. M. Lefroy: Exhibition of Cinematograph Films of the Housefly.—Dr. N. S. Lucas: Reports on the Deaths which have occurred in the Society's Gardens during 1922.—Prof. E. Lönnberg: Remarks on some Palearctic Bears.—E. W. Shann: The Embryonic Development of the Porbeagle-Shark, *Lamna cornubica*.—R. Gurney: Some Notes on *Leander longirostris*, M.-Edwards, and other British Prawns.

INSTITUTION OF CIVIL ENGINEERS, at 6.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Scientific and Technical Group), at 7.—A. S. Newman: The Causes of Static Trouble in the Kinematograph, and Means for its Elimination.

ILLUMINATING ENGINEERING SOCIETY (at Royal Society of Arts), at 8.—W. J. Jones, E. A. Marx, Jr., and others: Discussion on the Projection of Light.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—P. E. Newberry: The Beb Sed Festival of Ancient Egypt.

SOCIOLOGICAL SOCIETY (at Royal Society), at 8.15.—Prof. J. A. Thomson: Biological Contributions to Sociology.

WEDNESDAY, FEBRUARY 21.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. C. Pearson: Greek Civilisation and To-day (2), Progress in the Arts.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—R. L. Braithwaite: The Flow of Lymph from the Ileo-Cæcal Angle and its possible bearing on (1) the formation of Gastric and Duodenal Ulcer, and (2) the cause of other types of Indigestion.

INSTITUTION OF AUTOMOBILE ENGINEERS (at Institution of Mechanical Engineers), at 7.30.—Informal Meeting.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—Col. E. Gold and others: Discussion on Reform of the Calendar, by C. F. Marvin.—Dr. S. Fujiwhara: The Growth and Decay of Vortical Systems.—Dr. S. Fujiwhara: The Mechanism of Extratropical Cyclones (Third memoir on Vortical Phenomena).

ROYAL SOCIETY OF ARTS, at 8.—C. Ainsworth Mitchell: Handwriting and its Value as Evidence.

ROYAL MICROSCOPICAL SOCIETY, at 8.—Sir William Maddock Bayliss: Microscopical Staining and Colloids.—A. Mallock: Note on the Resolving Power and Definition of Optical Instruments.

THURSDAY, FEBRUARY 22.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. B. Melvill Jones: Recent Experiments in Aerial Surveying (2).

ROYAL SOCIETY, at 4.30.—G. I. Taylor and C. F. Elam: The Distortion of an Aluminium Crystal during a Tensile Test (Bakerian Lecture).

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. W. G. Savage: Canned Foods in Relation to Health (Milroy Lectures) (1).

INSTITUTION OF STRUCTURAL ENGINEERS, at 7.30.—E. Godfrey: Shear Resistance.

CHEMICAL SOCIETY (at Institution of Mechanical Engineers), at 8.—Principal J. C. Irvine: Some Constitutional Problems of Carbo-hydrate Chemistry.

CAMERA CLUB, at 8.15.—E. R. Ashton: Picturesque India.

FRIDAY, FEBRUARY 23.

ASSOCIATION OF ECONOMIC BIOLOGISTS (in Botanical Theatre, Imperial College of Science and Technology), at 2.30.—Sir John Russell, H. G. Thornton, and others: Discussion on Partial Sterilisation of Soil: Present Views as to its Effects and their Causes.

PHYSICAL SOCIETY OF LONDON, AND RÖNTGEN SOCIETY (at Imperial College of Science and Technology), at 3.—Demonstrations: Major C. E. S. Phillips: A Method of Measuring X-ray Intensity.—E. J. Evans: Intermittent Discharge from Sectorless Wimshurst Machine.—L. H. Clark: An X-ray Balance.—H. B. Gough: Ionometer.—W. E. Schall: Spectrometer for Measuring End-radiation.—Dr. F. L. Hopwood: The Ondoscope.

EUGENICS EDUCATION SOCIETY (at Royal Society), at 5.—Dr. L. Hogben: Intersexuality and Sex Reversal.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—E. R. Flint: Abnormalities of the Hepatic and Cystic Arteries and Bile Ducts.

PHYSICAL SOCIETY OF LONDON, AND RÖNTGEN SOCIETY (at Imperial College of Science and Technology), at 5.—Discussion on The Measurement of X-rays.—Sir William H. Bragg: Introductory Address.—Prof. S. Russ: The Measurement of X-ray Intensity and the Necessity for an International Method.—F. T. Harlow and E. J. Evans: The Quality of X-rays produced by Various Types of High-tension Generators and an Incandescent X-ray Bulb.—Dr. M. Berry: Practical Measurements for Medical Purposes.—Dr. G. W. C. Kaye and Dr. E. A. Owen: X-ray Protective Materials.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—A. J. Tracey: Characteristics, Operation, and Maintenance of Underground Cables.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. A. S. Eddington: The Interior of a Star.

SATURDAY, FEBRUARY 24.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Ernest Rutherford: Atomic Projectiles and their Properties (2).

BRITISH PSYCHOLOGICAL SOCIETY (at Bedford College), at 3.—Prof. T. H. Pear: An Examination of some Current Beliefs concerning Muscular Skill.—Miss M. MacFarlane: The Use of Mental Tests in American Schools and Clinics.

PUBLIC LECTURES.

SATURDAY, FEBRUARY 17.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Dr. F. A. Bather: A Limestone Cliff and the Animals that built it.

MONDAY, FEBRUARY 19.

KING'S COLLEGE, at 5.30.—Dr. W. Brown: Psychology and Psychotherapy (1). (Succeeding Lectures on February 26 and March 5.)

TUESDAY, FEBRUARY 20.

LONDON SCHOOL OF ECONOMICS, at 5.—S. P. Vivian: Statistics, before, during, and after the War: Population.

SCHOOL OF ORIENTAL STUDIES, at 5.—Dr. T. G. Bailey: The Sansis, or Thieves of India; their Language, History, and Customs.

KING'S COLLEGE, at 5.15.—Dr. J. H. Orton: The Bionomics of Marine Animals (1). (Succeeding Lectures on February 22 and February 23).—At 5.30.—Prof. H. Wildon Carr: Physical Causality and Modern Science (1). (Succeeding Lectures on February 27, March 6, 13, 20, and 27).—Prof. A. J. Toynbee: The Expansion of Europe Overland (1). (Succeeding Lectures on February 27, March 6, 13, 20, and 27.)

WEDNESDAY, FEBRUARY 21.

INSTITUTION OF ELECTRICAL ENGINEERS, at 5.15.—Prof. Miles Walker: The Control of the Speed and Power Factor of Induction Motors (1). (Succeeding Lectures on February 26, March 14 and 21.)

KING'S COLLEGE, at 5.30.—Prof. F. Soddy: A Physico-Chemical Theory of the Instability of Western Civilisation.

SATURDAY, FEBRUARY 24.

HORNIMAN MUSEUM (Forest Hill), at 3.30—S. H. Warren: The Interplay of Land and Sea.

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

"To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

38, HOLBORN VIADUCT, E.C.1.

LONDON.

UNIVERSITY OF LONDON.

A Course of three Lectures on "RECENT WORK ON INBORN ERRORS OF METABOLISM" will be given by PROF. SIR ARCHIBALD E. GARROD, K.C.M.G., F.R.S. (Regius Professor of Medicine, Oxford), in the ROBERT BARNES HALL at THE ROYAL SOCIETY OF MEDICINE, 1 WIMPOLE STREET, W.1, on WEDNESDAYS, February 28, March 7, and March 14, at 5.30 P.M. At the first Lecture the Chair will be taken by the VICE-CHANCELLOR OF THE UNIVERSITY (Mr. H. J. WARING, M.S., F.R.C.S.). ADMISSION FREE, WITHOUT TICKET. Syllabus obtainable on application to the undersigned.

EDWIN DELLER, Academic Registrar.

UNIVERSITY OF LONDON.

A course of four lectures on "ELECTRIC FIELDS IN ATOMIC PHYSICS" will be given by Professor E. T. WHITTAKER, F.R.S. (Professor of Mathematics in the University of Edinburgh), at UNIVERSITY COLLEGE, LONDON (Gower Street, W.C.1), on MARCH 13, 15, 20, and 22, 1923, at 5.15 P.M. At the first lecture the Chair will be taken by Professor L. N. G. FILON, F.R.S. (Goldsmid Professor of Applied Mathematics and Mechanics in the University). ADMISSION FREE, WITHOUT TICKET. Syllabus on application to the undersigned.

EDWIN DELLER, Academic Registrar.

MAGDALEN COLLEGE, OXFORD.

The EDWARD CHAPMAN RESEARCH PRIZE will be offered for competition at the commencement of Summer Term, 1923, for a published piece of original research in some one of the following departments of Natural Science: Physics or Chemistry, including the Sciences of Astronomy, Meteorology and Mineralogy, or Geology, or the Biological Sciences of Zoology and Botany, whether treated from the Morphological, Palæontological, Physiological, or Pathological point of view.

The competition is restricted to members of Magdalen College who shall have been in residence for a period of two years, and at the date of closing the competition shall be under 30 years of age, and shall not have exceeded seven years from the date of matriculation.

The prize is of the value of £20.

Candidates must send in their competing papers or memoirs not later than May 1, 1923, to Mr. R. T. GUNTHER, MAGDALEN COLLEGE, from whom further particulars can be obtained.

PRIFYSGOL CYMRU.
UNIVERSITY OF WALES.

THREE FELLOWSHIPS, tenable for two years, may be awarded in 1923 to Graduates of the University of Wales. The value of each Fellowship will be £200 per annum. Applications from Candidates for the Fellowships must be received before June 1, 1923, by the REGISTRAR, University Registry, Cathays Park, Cardiff, from whom further information with regard to the Fellowships may be obtained.

DERBYSHIRE.
MIXED SECONDARY SCHOOL.

WANTED, in September, a MISTRESS for Natural History, Zoology, and Botany. Salary according to Burnham Scale. Non-resident post. FUTURE CAREER ASSOCIATION, Roland House, Old Brompton Road, S.W.7.

BEIT FELLOWSHIPS FOR SCIENTIFIC RESEARCH.

NOTICE is hereby given that the TENTH ELECTION OF FELLOWS will take place on or about July 16, 1923.

Applications must be received on or before April 19, 1923.

Forms of application and all information may be obtained by letter, addressed to the RECTOR, Imperial College, South Kensington, London, S.W.7, England.

THE EXPERIMENTAL DEPARTMENT OF THE FINE COTTON SPINNERS & DOUBLERS ASSOCIATION

Invites application for the two following posts:

INSTRUMENT MAKER, with good general experience of high-class work, preferably used to experimental laboratory apparatus (electrical and physical). Wages about £4 weekly.

PHYSICS LABORATORY ASSISTANT, of Inter. BSc. or equivalent standard, must be specially interested in physics and keen to pursue training for research. Initial wage £3 weekly.

Hostel accommodation available.

Applications should be addressed to Dr. W. L. BALLS, Rock Bank, Bollington, nr. Macclesfield.

TO TECHNICAL CHEMISTS AND

Bacteriologists, Owners of Chemical Works having acquired favourable Process Licence invite technical and financial co-operation for establishing £20,000 unit plant for approved bio-chemical process showing over 100 per cent profit under present conditions. In first instance it is necessary to state in confidence, qualifications, experience, and capital available for approved enterprise. Box 1872/17, c/o NATURE Office.

M.Sc., PHYSICS, wishes to obtain Research

Post. Experience in Research and Demonstrating. Box No. 58, c/o NATURE Office.

UNIVERSITY OF SYDNEY, NEW SOUTH WALES.

PROFESSORSHIP OF PHYSICS.

The Senate of the University of Sydney invites application for the CHAIR of PHYSICS, to which is attached a salary of £1100 per annum together with rights to a pension of £400 per annum on certain conditions. The Professor appointed will be expected to enter on his duties on August 1, 1923; £150 will be allowed for travelling expenses from Europe.

Further details concerning the appointment may be obtained on written request to THE AGENT-GENERAL FOR NEW SOUTH WALES, AUSTRALIA HOUSE, STRAND, LONDON, W.C.2, to whom applications for the position, in sextuplicate, accompanied by copies of testimonials (if any), should be sent so as to reach him not later than Wednesday, FEBRUARY 28, 1923. There is no special form of application. All correspondence addressed to the Agent-General in connection with the appointment should be marked on the outside of the envelope "University of Sydney."

T. A. COGHLAN,
London, January 30, 1923. Agent-General for New South Wales.

IF YOU are Interested in Chemical or

Technical Books and Journals, let us send you our Catalogues—both new and second-hand. We are in the best position to meet your requirements, and will do so on the best terms.

WILLIAM BRYCE,
Scientific Bookseller,
54 and 54A Lothian Street, EDINBURGH.

W. WATSON & SONS require the services

of a JUNIOR OPTICAL COMPUTOR, with some experience of, and competent to test, instruments and lens systems. Arrangements could be made for attending at lectures, if desired. Reply in writing, stating age and experience, to 313 HIGH HOLBORN, W.C.

STUDENT'S MICROSCOPE FOR SALE

—Crouch, coarse and fine focussing, rotating stage, 1" and ¼" objectives, 2 eyepieces, mahogany case, good condition. £5. B. H. KNIGHT, Engineering Dept., University College, W.C.1.

SPECIAL MICROSCOPICAL SLIDE.—

Radium. Perpetually giving off numerous flashes of light. Post free, 2s. 3d. Two slides, 4s. 3d. DARLASTON, 31 Freer Road, Birchfield, Birmingham.

THE HANDBOOK OF PATENT LAW OF ALL COUNTRIES

By W. P. THOMPSON, F.C.S., M.I.Mech.E., Etc.,

Chartered Patent Agent of Liverpool.

Entirely revised and rewritten 1920. 157 pages. Crown Octavo.

All Countries, 6s. British Law only, 1s.

"Should prove a very valuable and trustworthy guide to would-be patentees."—*Nature.*

LONDON: STEVENS AND SONS, LIMITED.

MESSRS. SOTHERAN

have now opened a Scientific Department on the first floor of their Strand House, where a selection of their large stock in modern, as well as old and rare, works on Exact and Applied Science may be seen on the shelves.

They would also call attention to their facilities in getting sets or runs of periodicals on scientific subjects, as well as rare or out-of-print books they may not have in stock already.

HENRY SOTHERAN & CO., 140 STRAND, W.C.2, & 43 PICCADILLY, W.1, LONDON.

RADIUM ON HIRE

(Activity 1,800,000).

RADIUM MICROSCOPES,

Complete with Radium, 2/6 and 7/6 each.

These are SELF-LUMINOUS in the dark,

showing splendid Scintillations.

Pitchblende Scintilloscopes . . . 7/6 each.
Extra Screens for Testing Minerals . 1/6 each.

F. HARRISON GLEW,

156 Clapham Road, London, S.W.9.

Telephones: 1787 Hop and 3117 Hop.

Intellectual Regimentation.

SIR MICHAEL SADLER has done a good service, "one stroke of faithful work," by envisaging again the question whether teachers should be Civil Servants. The title of this article is one of many happy phrases in his brilliant, if not altogether conclusive, address at the annual meeting of the Assistant Masters' Association. Our present measure of freedom from State control in education, he said, was the possibility of resisting, if the need arose, "intellectual regimentation." Against this important but contingent attribute of intellectual freedom, the primrose path of State control of education appears to lead to rare and refreshing fruit for teachers. One of the *sequelæ* of the Burnham salary scale with its regular increments has been that senior assistant masters and mistresses in secondary schools run considerable risk of being displaced by younger teachers entitled to lower salaries under the scale. It is stated indeed that teachers have been dismissed in this way purely on grounds of economy. In any event, there must be a tendency under existing conditions for the teaching profession to become immobile.

State control of education would offer to teachers security of tenure, fair if not generous salaries and pensions, an impartial system of promotion and transfer. It would secure greater uniformity in the work and organisation of our schools, a higher standard of scholarship and training in the teaching profession, and a stricter discipline. These results have been attained more or less completely in France and Germany, where the influence of the State on education is more "decisive and peremptory" than in Great Britain. English-speaking countries have usually preferred to leave the appointment of teachers in the hands of local boards, corporate bodies, or individual employers.

But with the Labour Party definitely committed to a policy of nationalisation on a large scale, the question of State control of education in Great Britain cannot be regarded as purely academic. Sir Michael Sadler, while expressing his personal preference for our present system, thought the trend during the last five years had been in the direction of State control. Mr. Fisher's Superannuation Act for teachers, for example, was closely modelled on the Civil Service pension system. Further, the finance of public education has in recent years become so chaotic that the magic wand of bureaucratic control may be invoked to produce some sort of order. We must not forget that, two generations ago, under somewhat similar conditions as regards the standard and efficiency of elementary education, Mr. Robert Lowe introduced the system of "payment by results"; a system which its author commended on the

ground that the nation would be assured of value for its money. In the present distressing condition of the national finances, the president of the Board of Education may be searching for some empirical solution of our educational troubles which he could commend for the same reason.

If the straight issue be joined between intellectual freedom and bureaucratic control, we have no doubt that in the present temper of the public and of the teaching profession, the decision would be emphatically against bureaucratic control. In the recent educational conferences, the point of view of the teachers on this question was expressed without reservation or ambiguity. The fact is the war has produced a marked mistrust of "regimentation" in any form, mistrust of both its methods and its results. English people, in accord with their history and traditions, will show great caution in adopting any form of organisation which may tend to thwart the free growth and play of personality and the full exercise of political freedom. By ensuring the ninety-nine parts of education which is diligent and orderly routine, we must not stifle the hundredth part, which is art.

This, however, is not to say that the problem of the relation of the State to education does not exist. On the contrary, the question of State control is encountered not only in education but also in other professions such as medicine and the promotion of scientific research, and, more urgently perhaps, in the extensive field of industry. Any advance in dealing with the question in one aspect must affect others and orientate the national mind towards a general solution. We plead, therefore, that the best creative thought of our teachers, men of science, and statesmen should be dedicated to the question of defining the true function of the State in various departments of our national life.

Without attempting to explore the question in all its implications, we would suggest that if in any particular case State control or nationalisation is found to be the best solution of existing difficulties or the best policy for the future, its form should be adapted to special conditions. In teaching and scientific research particularly, spiritual values must be conserved, mechanical methods avoided, and the workers themselves as the real experts must be assured a fair share of direction and control. Some amount of "intellectual regimentation" may be necessary in the fight against ignorance and vice and in attacking complicated scientific problems. But from neither the teacher nor the scientific worker will the best results be obtained if their direction and control come from an authority which they may regard as external, ignorant, unsympathetic, and autocratic. In submitting these observations, we are in no sense attacking the policy of the Labour Party or any other political party. An eminent politician has suggested that we are all socialists nowadays. This is true in the sense that our work is directed in an increasing measure to the good of the community. The question of State control is one of method and machinery rather than of ideal, and should be studied in a cold scientific light, without personal or political prejudices or vituperation.

Formalism and Mysticism.

Tractatus Logico-Philosophicus. By Ludwig Wittgenstein. (International Library of Psychology, Philosophy and Scientific Method.) Pp. 189. (London: Kegan Paul and Co., Ltd.; New York: Harcourt, Brace and Co., Inc., 1922.) 10*s.* 6*d.* net.

READERS of Mr. Bertrand Russell's philosophical works know that one of his pupils before the outbreak of the war, an Austrian, Mr. Ludwig Wittgenstein, caused him to change his views in some important particulars. Curiosity can now be satisfied. The "Tractatus Logico-Philosophicus" which Mr. Ogden has included in his new library of philosophy is a remarkable and strikingly original work. It is published in German and English in parallel pages. It is difficult to appreciate the reason for this, seeing that the author is evidently familiar with our language and has himself carefully revised the proofs of the translation. Also we should have liked to have the Tractatus without Mr. Russell's Introduction, not, we hasten to add, on account of any fault or shortcoming in that introduction, which is highly appreciative and in part a defence of himself, in part explanatory of the author, but for the reason that good wine needs no bush and that Mr. Russell's bush has the unfortunate effect of dulling the palate instead of whetting the appetite. In his penultimate sentence Mr. Russell says: "To have constructed a theory of logic which is not at any point obviously wrong is to have achieved a work of extraordinary difficulty and importance." We agree, but how uninspiring when compared with Mr. Wittgenstein's own statement of aim: "What can be said at all can be said clearly, and whereof one cannot speak, thereof one must be silent."

In fact, when we come to the root of the matter there seems to be little in common between pupil and teacher. When we read Mr. Russell's works we feel indeed that what we can know of the universe is little enough in comparison with what we can never know, but yet he recognises no limit to the logical classification of its constituent entities. Indeed he seems to aim at an exhaustive inventory, at least of classes. Mr. Wittgenstein, on the other hand, makes us feel with Spinoza that our knowledge is limited to

two modes of the existence of a being who himself exists in infinite modes.

The Tractatus consists of seven main propositions, six of which admit of expansion and aim at saying clearly what can be said. The seventh admits no expansion. It affirms the limit of what is expressible, the inexpressible, and it acquiesces in silence. In its form, the Tractatus recalls the Monadology of Leibniz; in its content, it approximates, as we have indicated, to Spinoza. Logic is the ladder by which we rise to a vantage-point from which we survey reality, but when we have risen we recognise that the logical propositions which have supported us are in themselves meaningless: we must throw them away in order to see the world rightly, and then, face to face with reality, we find it is inexpressible.

The six main propositions are the rungs in the ladder. (1) The world is everything that is the case. (2) What is the case, the fact, is the existence of atomic facts. (3) The logical picture of the facts is the thought. (4) The thought is the significant proposition. (5) Propositions are truth-functions of elementary propositions (an elementary proposition being a truth-function of itself). (6) The general form of truth-function is (omitting the symbols and substituting the interpretation) that every proposition is the result of successive applications of the operation of negating all the propositions making up any set of propositions, to the elementary propositions. The seeming obscurity of this last sentence may perhaps be removed by a quotation. "The propositions of logic demonstrate the logical properties of propositions, by combining them into propositions which say nothing. In a logical proposition propositions are brought into equilibrium with one another, and the state of the equilibrium then shows how these propositions must be logically constructed."

These six main propositions are not elaborated in the deductive or analytic manner, but it is shown that a number of propositions depend upon them in a way which proves that logic is a constructive process. It will be seen, then, that the Tractatus is not a book to be read cursorily; every proposition will only be understood if the reader succeeds in himself thinking the thought of it. Its appearance is a notable event in the philosophical world and will be received in many quarters as a challenge.

Probably the central point of interest is the meaning which Mr. Wittgenstein attaches to what he calls the atomic fact. Outwardly it appears to agree with what Mr. Russell describes generally as logical atomism, but when we get down to the atomic fact itself, it becomes as different from Mr. Russell's description of the constituent element as the modern scientific conception of the atom is different from the Democritean. For Mr. Wittgenstein the atomic fact is a system. "In the atomic fact objects hang one in another like the members of a chain." Further on he tells us we must not say, "the complex sign *aRb* says *a* stands in relation *R* to *b*"; what we must say is "*that a* stands in a certain relation to *b* says *that aRb*." If we accept this, what is left of the famous theory of relations? Also to Mr. Wittgenstein those well-known nonsense propositions which play so large a rôle in the Russellian logic are nonsense, that is, they are not propositions, they are nothing.
